Allman suggests that this passage should be read as Gramsci encouraging leaders or radical educators to help people question their already existing knowledge (common sense thinking) until it becomes 'critical activity' (dialectical thinking) (Allman, 2001: p. 11; Hatton, 2008: pp. 45–47).

Gramsci's ideas are important because they not only encapsulate the idea that people can take action to challenge unequal power relationships, but they also show how hegemonic or ruling ideas are transmitted. This then clarifies how ideas about how society is constituted, and then reconstituted. These are important considerations for community workers wishing to develop a more transformative practice.

Paulo Freire

Paulo Freire was a Brazilian educator, and at one time, Secretary of Education for Sao Paolo (Freire, 1993). Mayo (1999) describes Freire as possessing, "a vision of society characterised by relations of power and domination" (p. 59). His key ideas revolved around:

Agency – the ability of people to act in their own interests, but their capacity to 'act' can be impacted upon their psychological and social experiences.

Democratic Education – based on the idea of promoting education through *dialogue*, "the encounter of men [sic] in the world to transform the world" (1972: p. 100), as an alternative to conventional education. Central is the notion of praxis, the linking together of action and reflection.

Conscientizaçao (conscientization) is the key concept Freire used in enunciating how this will operate. Freire sees "education as an exercise in freedom, is an act of knowing, a critical approach to reality" (Mayo, 1999: p. 63). In Freire's words, "that lived experience be used as a point of departure so as to transcend it" (Freire, 1993: p. 110).

These are important processes if "human services practice is to become an emancipatory project, rather than a reinforcement of existing patterns of discrimination" (p. 215). Freire (1972) argues that a key way in which people without power are marginalized is through a process in which their behavior becomes pathologized and their human nature is distorted to construct what he describes as processes of indoctrination, manipulation, and 'dominated consciousness.' He argues that as a result, people lack the consciousness or understanding to decode their situations. Thus, he proposes a process of deindividualization, by which people are encouraged to see the commonality of their situation. Central to Freire's work is the idea of dialogue. Having established the importance of linking theory to practice, I look briefly at examples of the way in which this link has been expressed in community work.

Exemplifying Community Work/Community Action

Community Development Projects

The work of the Community Development Projects (CDP's) within the UK reflects earlier debates around the nature of community work. The introduction of the Community Development Projects in 1970 was initially seen as "a neighborhood based experiment" whose focus was on meeting the needs of people in "areas of high social deprivation" (CDP, 1974a: p. 1). The projects were originally based on a social pathology model of deprivation that assumed that the "problems of urban deprivation had their origins in the characteristics of local populations – in individual pathologies – and these could best be resolved by better field coordination of the social services, combined with the mobilization of self-help and mutual aid in the community" (1974a: p. 1).

By the time the CDP (1974b) *Inter-Projects Report* was published in 1974, many of the projects had changed emphasis and had moved toward a structural analysis of the urban deprivation that the communities that they were dealing with suffered from.

The arguments against social pathology were extended in the joint report, *Gilding the Ghetto* (CDP, 1977). The authors argued that, the major cause of poverty during the 1960s was the decline of the industrial base of the older areas. They pointed out how it was useful to the state to continue to define the problems of working class areas as due to as individual pathology. As they noted "the emphasis on tackling social needs in isolation inevitably distracts attention from the root causes of the problem by focusing attention upon personal deficiencies" (Craig et al., 2011: p. 95).

Assessing this Report's impact, Shaw (2003) suggested that "its title conveyed a powerful metaphor for the ideological value of 'community' in glossing over the structural causes of poverty and inequality" (p. 363). Shaw and Martin (2000: p. 404) suggested that the structuralist/Marxist analysis that the CDPs formulated represented "community work's potential to be both 'in and against' the state" (Shaw and Martin, 2000: p. 404).

Locally Based Community Development – Examples from Ireland and Wales

I have interviewed people working in community development projects in Wales and Ireland (Hatton, 2001). The project

leader in *We, The People*, a community development project in Cork, in Eire, argued that empowerment was a central issue for their organization:

> The empowerment aspect of it comes down to giving power back to people and making structures available to support them. But at the end of the day it's their power. By empowering someone you are giving them the power … the object of the organization is to empower people … you need to rebalance the power.
>
> Hatton, 2001: p. 209

A community worker in Cardiff, South Wales suggested that the challenge was to give people a belief in the efficacy of change, but suggested that:

> It's not realistic to believe that people on their own can achieve lasting change … we need a younger, more radical group to overcome the alienation people face. The focus should be on collective change at the political level. However, I am optimistic. I believe people are irrepressible, they will make demands.
>
> Hatton, 2001: p. 209

The Director of Community Action Network (CAN) also based in Cork suggested that this is one of the central elements of a community development approach:

> the vision that community development provides is one of promoting social change and that supporting communities to become more active and more empowered was a worthwhile exercise and if there was a gap in services it was worth pursuing.
>
> Hatton, 2001: p. 206

Community Development in Central Europe

Henderson and Vercseg (2010) have drawn attention to the way community development in Hungary grew out of community education and was influenced by ideas developed by Hungarian intellectuals influenced by Gramsci. They suggest that community development was influenced by two key approaches – social reform and foreign funding organizations or nongovernmental organizations (NGOs). There is also some evidence from the Czech Republic, of the growth of indigenous organizations who have developed what McLaughlin (1995) has called their own "ethnic intelligentsia" (a phrase he developed to describe the growth of an indigenous leadership within the Irish Traveling community). The development of Romdromas, a Roma-controlled organization negotiating directly with state and regional government bodies, 'Sduzeni Dzeno,' a Roma-run internet radio station, and the establishment of 'Evangelika Akademie Prague,' to train Roma as social pedagogues are examples of Roma peoples developing their own organizations and indigenous leadership (Hatton, 2008: pp. 133–138).

Community Youth Development

Perkins et al. (2001) apply ideas from community development in their discussion of community youth development (CYD). They suggest that CYD "shifts the emphasis from a dual focus of youth being problem free and fully prepared, to a triadic focus for youth being problem free, fully prepared and engaged partners … .[T]his focus recognises that there is an interdependent relationship between positive and healthy youth outcomes and positive and healthy communities" (p. 43). Perkins et al. (2001) suggest that community youth development at its core focuses on the young person's capacity to both understand and act upon the environment, a recognition that this involves the active support of people across the community. Central to such work is the engagement of youth in "constructive and challenging activities that build their competence and foster supported relationships with peers and with adults" (p. 48). Finally, Perkins et al. suggest that achieving these goals requires developments in youth participation and partnerships within the communities in which young people live.

NGOs and Community Development

Community development is an approach which is typical of many NGOs particularly those operating in African and Latin American contexts. Kamat (2004) suggests that:

> The presence of numerous NGOs at the grassroots that provide services to underprivileged populations, and at the same time mobilise them for their rights, presents a threat to the neo-liberal agenda of privatisation … In countries of the South, the Leftist origins of (NGOs) are reflected in their opposition to structural adjustment policies.
>
> Kamat, 2004: p. 167

Princen (1994) argues that NGO influence is:

> achieved by building expertise in areas diplomats tend to ignore and by revealing information economic interests tend to withhold … it is influence gained from speaking when others will not speak, from espousing something more than narrow self-interest, from sacrificing personal gain from broader goals, from giving voice to those who otherwise do not have it, from rejecting pessimism and looking for signs of hope.
>
> Princen, 1994 quoted in Betsill and Corell, 2001: p. 70

During the 1980s and much of the 1990s, the United Nations was highly responsive to the demands of the NGOs for participation and created important institutional space for NGOs to demand to participate in international policy forums on population, the status of women, and the environment (Kamat, 2004: 162).

Social Pedagogy and Community Development

Eriksson (2011) has pointed to the differences and similarities between community development and social pedagogy (Hatton, 2013: pp. 82–87). The former, she attributes to their differing origins (community development as a way of thinking, the latter as a way of doing); to the geographical spaces they occupy (European as against Anglo-Saxon); to the differing welfare regimes in which they operate; and to the way in which social pedagogy can be formulated as an

individual intervention while community development is by definition a collective response to the problems people face. However, Eriksson argues that there are clear similarities. Both provide a holistic understanding of education, development, and learning. She suggests that in both traditions, there is, "a tension between a radical and a conservative side" and that these raise the question of whether "the individual, society or both should be the focus of change" (Eriksson, 2011: pp. 414–417).

Lone (2010) raises similar issues when discussing the work of treatment collectives in residential care for people who misuse substances in Norway. She argues that because these agencies lack a hierarchy, there has been a "strong and radical political bias" (p. 62) which has allowed them to provide an alternative social pedagogy to the medicalized services available elsewhere. This, Lone argues, is partly to do with skepticism in Norway toward all kinds of residential care and quotes Edle Ravndal, who in a review of the working of collectively organized services suggests that:

> The collective model seems still to defend its place as an important component in a larger treatment system for the most challenged youths.
>
> Lone, 2010: p. 70

Social pedagogy and community development therefore appear to share the potential to transform people's experience and create new ways of delivering and experiencing welfare services. They can connect with traditions whose focus has been on promoting change not merely ameliorating the impact of inequality and disadvantage (Hatton, 2008, 2011).

Globalization and Community Development

Macionis and Plummer (2005: pp. 38–39) suggest that globalization had a number of elements that impact upon community work and community workers. These include:

- The development of new forms of international governance, e.g., the UN, ECHR, WHO.
- A growing awareness of common world problems.

Reviewing the welfare literature on globalization, Lyons et al. (2006: p. 37) suggest that the authors see the, "fragmentation of old arrangements; damaging effects upon general living standards and economic security; and pressure to reduce expenditure on welfare (in order to be competitive) … social problems are becoming increasingly globalized and … consequently social workers … must take account of events, institutions and policies beyond national and even regional borders."

The most effective way of achieving this goal is through engagement in forms of collective action which can help transform the meaning of everyday life and which can act as 'revealers' by exposing that which is hidden or excluded by the decision-making process. "Collective protest and mobilization bring to light those elements of silence, obscurity or arbitrariness buried within complex systems" (Melucci, 1989: p. 175). Craig (1998) argues that understanding the global context as it impacts on communities is important because, "throughout the world oppressed people have found a voice in part through the work of community development activists" (p. 15). Dominelli (2010: p. 172) makes a similar point when she argues that a focus on globalization can allow us to "bring marginalized areas of practice into the mainstream, particularly those linked to indigenous knowledges and new areas of endeavour."

Conclusion

Community work has a varied and complex history. As Mayo (2008) has suggested it has in many ways reflected the changing social, economic, and political conditions of the last century. She points to the tension within community work between those community workers:

> Who have preferred to fix their eyes on the gutters, rather than the stars, to concentrate on everyday issues rather than think strategically about how to effect change.
>
> Mayo, 2008: p. 16

This article has attempted to demonstrate how it is possible to fix your eyes both on the gutter and think strategically. It is precisely through this focus on action and theory that a meaningful community work can be sustained and contribute to resolving the wide range of social, economic, and political problems facing marginalized communities in the twenty-first century. As Henderson and Vercseg (2010) note:

> Community development can help civil society retain the dimension of challenge … the contribution that community development can bring are the experiences, learning and key messages of communities (p. 177).

The wide range of interventions described earlier indicate how this process of challenge can be maintained through the contributions that community work/development can make to these processes.

Abstract

The social context of community encompasses varied geographies as well social relations embedded in a network of relationships. The context of social communities is not necessarily spatially bound, although the context may originate in particular localities; social networks, identity, and new technologies allow social communities to cross geographies to encompass the entire globe. Thus, the social context of community varies from communities where space defines the social community to those where affinity does. Varied contexts have differential impacts on individuals and their access to opportunity, social support, social capital, involvement in civic life, and engagement in social movements.

The social context of community encompasses varied geographies as well social relations embedded in a network of relationships. The context of social communities is not necessarily spatially bound, although the context may originate in particular localities; social networks, identity, and new technologies allow social communities to cross neighborhood and city boundaries to encompass the entire globe. Thus, the social context of community varies from communities where space defines the social community to those where affinity does. Community's social contexts can be found in local geographies (like neighborhoods and local governmental units), institutions (such as voluntary organizations and churches), in the spaces of everyday life (such as work, school, and home), through extended family relationships, and through national and global affiliations and concerns.

The Influence of Community Social Context

The social contexts in which community occurs are theorized to have varied impacts on the lives of individuals, ranging from being the source of social support to information about varied life opportunities to the context of social action. These resources flow through the social networks in which individuals are embedded, and that act as vital links to larger social systems. Networks affect the flow of resources and information to and from the individual (Lin, 2001); the relationships among individuals occur and vary in the context of this complexity. Additionally, the structure of social networks themselves can work to create a community social context that influences both helping relationships and economic advancement differentially.

The implication is that community social context can influence social capital – the flow of resources and information across people through social networks; relationships with others may facilitate action, provide information, or make connections between the microlevel and the macrolevel. Coleman (1988) outlines three types of social capital. First, he describes relationships of help, obligation, and trust. Second, he discusses social capital as the possibility for information that facilitates action. Third, norms also arise through social relations, providing a social context that can facilitate certain actions and constrain others. While social capital can variously provide social support or social leverage or be a link to social resources (Lin, 2001), the use of such ties varies with the social context in which they are embedded. As Alejandro Portes (1998) notes, ties that provide social support may facilitate social control but may not be the same ties that provide help in finding a job. Furthermore, ties that provide social support clash with those that enable social leverage, if local norms must be overturned to facilitate economic action.

Urban and Rural Contexts

In the face of rapid urbanization in the late nineteenth century, Tonnies suggested that social communities were different in urban and rural places. He characterized ties in rural areas as strong interdependent relations – *Gemeinschaft* – while in urban areas social ties are more distant – *Gesellschaft*. The notion was that people in urban areas are isolated from kin; ties are attenuated. Urban sociologists Wirth and Simmel suggested that there were fundamental differences in urban relationships that make them more distant, alienating, and instrumental than those in rural settings. Yet, the community studies of the mid-twentieth century demonstrated that neighborhood was a locale for social ties, especially in working class and poor areas. For lower income residents in urban areas, survival may depend on interactions with this core network, often comprising kin and friends who find themselves in similar situations.

In suburban environments in the United States, scholars have commented on the attenuation of community at the neighborhood level. In particular, the writers of the third quarter of the twentieth century viewed low-density suburbs as the negation of community and communal relationships. Sprawl has been viewed as weakening household connections to immediate neighbors because it reduces spontaneous social interactions. While those with lower incomes have more ties within their neighborhoods, as do women and married people, those who live in car-dependent neighborhoods tend to have fewer ties to neighbors.

Neighborhood as Community's Social Context and Access to Opportunity

These ideas about the limitations of communities based in neighborhoods for people living in poverty arise again in the late twentieth century, most famously highlighted in William Julius Wilson's (1987) *The Truly Disadvantaged*, which outlined the social and economic isolation of the urban poor in Chicago and other cities. The idea was that over time middle class families left inner city neighborhoods for the suburbs, leaving behind a neighborhood social context devoid of social ties and economic linkages that could provide access to social and economic opportunity. Over time, a large literature grew to investigate neighborhood effects, focusing on the isolation of these inner city neighborhoods and the neighborhood effects on the life chances of individuals (Jencks and Mayer, 1990).

The notion that community social context can influence social and economic opportunities has become the focus of affordable rental housing policy in the United States (Joseph et al., 2007). The idea is that community of residence influences access to beneficial social networks, social control at the community level, behaviors leading to work and responsibility, and working institutions. Of these, only the latter has both theoretical and empirical support.

Community of residence influences the type of nonkin that people associate with but not their number, and those who are involved with neighbors are those with few sources for relationships outside the neighborhoods. As Fischer (1982) comments, "Those who are most involved with neighbors tended to be those with few sources of extra-neighborhood (nonkin) ties elsewhere," meaning those not working or working part-time, those new to the city, and those committed to home by marriage or home ownership.

Along with proximity, homogeneity is a key condition for affiliation. Michelson (1976) suggests that spatial proximity is only effective in encouraging interaction when there are conditions of real or perceived homogeneity and where there is a need for mutual aid, like small house repairs. Homogeneity – as far as stage in the life cycle, home ownership (and thus proprietary interests), life styles, and values – is the basis for social relationships, and may be more important than propinquity. McPherson et al. (2001) comment that the most basic source of homophily is space – we are more likely to have contact with those who are closer in geographic location than those who are distant. Thus, neighborhood can be an important social context due to both propinquity and perceived homogeneity.

Social Networks and Economic Action within Communities

Generally, the more diverse the types of people to whom an individual has access, the more different types of information available to that person, and the more likely he or she will experience better outcomes when looking for a job. Yet, the capacity for varied and valuable information varies within communities and the ability to use such information also varies across demographic groups. Generally, the greater the range of an individual's social network – the more diversity, the larger it is, the more it contains people who are not close to the individual, and the less everyone in the network knows everyone else – the more access to different societal circles that social network may be able to provide. Since the social context that arises through social network relationships tends toward homogeneity, such a breadth of contact with different social spheres creates a more varied community social context for that individual and therefore is helpful for gathering information. Granovetter's (1995) concept of the strength of weak ties suggests that the ties that provide access to a more varied social context are that weak ties – those that are short in duration, not emotionally close, not mutually confiding, infrequent, and not necessarily engaged in reciprocal services – reach out of homogenous cliques to allow for diversity of information and contacts. Yet, in some social groups, finding jobs through contacts may be the best option, but the jobs will be of poor quality because those are all the group has to offer. Working-class ties may lead to jobs, but jobs from same-group contacts may lead to jobs that are no better than anyone else's in the group.

While Granovetter's hypothesis about the nature of helpful social resources – the strength of weak ties hypothesis – provoked a generation of research on job matching, unmeasured social and human capital and the information available to the searcher may be more important than weak ties. Furthermore, some argue the very social structure of personal communities is part of the matching process that influences posthire outcomes, and that network structure alone, and not the type of tie used, is important. That is, the context of the social community delineated by such ties may be influenced not only by the type of information available but the very structure of that community, although the relative importance may vary by race, gender, and immigrant status.

While whites in urban environments may tend to become more involved with subcultures of interest, research suggests that blacks do not appear to be involved in minority subcultures. Urban blacks have social networks that are more racially diverse and less dense than those of rural blacks. Furthermore, while ethnic relations may enable job finding, support, and opportunities, they may also constrain them if the ethnic ties are not connected to a realm of relations with useful job information. For African-Americans, the level of racial diversity within their networks may be an important factor in having a good job as the outcome of a job search. Furthermore, personal contacts may facilitate transitions to employment, and African-Americans may face more barriers to employment when using their personal tie. For blacks, the degree to which people in the network fulfill multiple roles – such as concurrently being neighbor, coworker, and kin – is associated with finding lower paying jobs than other blacks, while the opposite was true for whites. The information available within the network is what is important, not simply the structure (Green et al., 1999; Coverdill, 1998). The racial diversity of the network is a proxy for the quality of the information available. Even if ethnic networks contained quality information, it is not enough for quality information to be present in a network, but other conditions must also exist that are part of positive social capital, namely, trust, mutual obligations, and social norms functioning through social networks (Smith, 2003). That is, the collective efficacy of the community is the context for the use of social ties in job finding; without it, individuals have no motive to help each other.

For women, spatial and social constraints converge to create a social context that does not always support economic advancement. Socially, as Jeanne Hurbert's work shows, gender homophilous contacts can have a significant negative effect on the socioeconomic status of the job sought. Furthermore, women who have diverse and large networks are more likely to be working for pay, and network bridges to those of better education and people outside the neighborhood may enable women to use their social networks more effectively to find a job. These effects must also be considered in concert with space–time constraints due to household responsibilities – women face a limitation on the range of employment opportunities open to them as compared to those available to men. Very low-income women may be much more likely to experience a spatial constraint in the job search because of their dependence on social ties, direct application, and falling into opportunities without a search. Furthermore, African-American women and their social networks may be more spatially bounded. The spatial boundedness of poor women may lead to increased opportunities for social support while reinforcing economic constraints. Thus, the community bounded both by space and structure – tie homophily – may be limiting for economic gain.

Migrants' social networks often center on other migrants and expand outward (Massey et al., 1987). For some immigrants, these social relationships may be limiting, but for others, network characteristics and the individual's personal position within them may allow them to mobilize resources. The social community in ethnic enclaves, as Alejandro Portes (1998) outlines, may provide vital resources for firms – providing not only start-up capital but also tips about business opportunities. However, Portes notes that impoverished communities with fewer of the characteristics of thriving ethnic enclaves also tend to lack these types of social connections. The circumscribed nature of personal social ties within the enclave may cut off information.

Hagen (1998) and others note that these social network resources vary for different people or groups in ways that impact opportunities. In Hagen's study of Mayan immigrants in Houston, ethnic ties allowed both men and women to work, but in entirely different fields that transformed social networks in distinct ways. Men's social worlds were able to support bids for legalization, while women's social worlds, as domestic help, did not. This is a repeated pattern in the migration literature.

Social Context, Intergroup Contact, and Tolerance

Neighborhood as the social context for community also may have a role in bringing people together who might not otherwise meet each other. Gordon Allport's (1979) contact theory suggests that people of different backgrounds will be more likely to interact if the groups have equal status when interacting within a given situation, are able to work toward common goals, have intergroup cooperation, and have support from authority for positive contacts. That is, just living in the same neighborhood or next to someone is not enough, but rather equal status, supported, and goal-oriented contacts are vital to positive changes in attitudes. Furthermore, Thomas Pettigrew (1998) suggests a fifth condition – that the contact situation must allow participants the opportunity to become friends. Thus, while neighborhood may be one context for social community, such relationships only occur in the appropriate circumstance, such as through community building activities.

Communities of Affiliation and Social Support

Communities of affiliation arise within spatial communities – such as neighborhoods – or through membership, the perception of a common cause, or the perception of homogeneity. Fischer's (1982) subcultural theory of urbanism encompasses these ideas, and suggests that people form social ties based upon many other attributes than kin and locality. Relationships are formed based upon ethnicity, occupation, lifestyle, and other common traits. Within these communities, people find "fellowship, guidance, and meaning…" (Fischer, 1982). Barry Wellman's (Wellman, 1979; Wellman and Leighton, 1979) work delineates three perspectives on the social context within urban neighborhoods: the community lost perspective of early urban sociologists, the community saved perspective presented in community studies, and, lastly, his suggestion of a community liberated – where kinship ties are important, but not primary, and people create 'personal community networks', a set of active community ties. These relationships are socially diverse, spatially dispersed, sparsely knit, and not spatially bound by the neighborhood. In urban areas people are less involved with neighbors than are those in small towns. People in cities turn to neighbors only if they find them compatible in some way (Fischer, 1982).

Thus, social support also can arise out of community social context, most frequently associated with dense, strong, and homophilous ties rather than weak and heterophilous ties. Informal support arises from core, homogenous networks. Increased network density, strong ties, homogeneity combined with a sense of belonging, and a high degree of normative consensus associated with these high levels of social integration help to facilitate a routinization of support among people in the core network.

Furthermore, where weaker ties may provide information, a relatively small number of emotionally strong ties likely provide broader support in terms of emotional aid, services, and companionship. While physical access – like being a neighbor – can promote both large and small services among people, physical access is not related to receiving social support in the form of companionship, emotional aid, and financial aid because these can actually be offered over large distances. Interactions in group settings do not foster social support, and the involvement of kin in a social support system is based on the aid of a relatively small number of immediate kin. Women tend to provide more emotional support than men.

Yet, the network is more than the sum of the one-on-one relationships, because the network as a whole can exert group pressure to provide support. Furthermore, such network capital functions on many different levels, based on the individuals social status, the size of the network, the similarity of people within the network, the availability of resources within the network and their ability to be delivered, the history of support and reciprocity, the composition of the network, the structure of information flows through the

network, and indirect ties. Different levels of network are nested within others.

The extent to which the social context of a neighborhood matters for social support depends on the type of aid needed (Wireman, 1984). People tend to use friends when they need to agree about tastes or if longer term support is needed. Neighbors are best at everyday contact that does not require a long-term commitment. Research has found that those who are economically advantaged have larger networks because they are more integrated into the larger society. As such, they do not need strong links to neighbors for day-to-day support. Those of lower socioeconomic status, however, because of a relative lack of social integration and more tenuous financial status need nearby support and cultivate it within their neighborhoods. In short, those who are poorer, more tied to their neighborhoods, and are less mobile tend to be more tied to their neighborhoods for their day to day social support needs.

Community Institutions as Social Context

Alexis de Tocquville's admiration of the young United States' democracy and consistent involvement in community associations contrasted with the 1830's French state-dependency of its citizens. Local civic groups, linked to small autonomous governments were the lifeblood of the young American Democracy. Over a 150 years later, Robert Putnam (2000) outlines the decline of US civil society and community trust, suggesting a decline in community-level social capital – a decline in joining these civic organizations. Berry et al. (1993) found that citizen participation can be dismissed as troublesome; at the same time, voluntary organizations can make outstanding achievements, despite these attitudes of civic officials. The collectivity that arises within localities or voluntary institutions can be a source of political voice and action.

Citizenship, Nations, and Globalization

Citizenship confers more than membership in a nation – it confers rights. T.H. Marshall suggested that citizenship is a core concept linking citizens to the nation. Every citizen of a nation has rights that range from minimal to extensive and included the rise of egalitarianism. These rights are insured by a national welfare state, government agencies, and the justice system. However, national centralization varies across nations, as does the egalitarian nature of citizenship. And over time, social upheavals among European Eastern Bloc countries led to a movement away from centralized control and radical egalitarianism.

The Western notion of a social contract preserves notions of egalitarianism in the obligations that citizens of a state have to each other. Social connection, Iris Marion Young argues, is prior to the institutions of the state. In a Lockean view of the social contract, the need and desire for social institutions arise from socially connected individuals who recognize that their relationships may conflict. The obligation of justice is generated by the social connections, and political institutions are responsible for those obligations. Membership within a nation-state thus involves a set of rights and responsibilities.

In a period of globalization of economies and international migration, political upheavals leave people as refugees without a membership in a nation. In contrast to John Rawls' nation-state-based conception of the social contract, Seyla Benhabib argues that the world community should be viewed as a global civil society. People are organized into nation-states, and such states are major players – but not the only players. Those who are without national status – refugees in this globalized world – still have basic rights accrued to them as humans. Thus, the claim to membership is not limited only to those with a national identity.

The Networked World

Some feared that the growth of the Internet would bring with it a loss of personal relationships and a loss of local community. Barry Wellman and Caroline Haythornthwaite (2002) argue that virtual communities extend the social context for community. The Internet, rather than being separate, facilitates all sorts of community ties. It enhances the resources for social support. Rather than reducing interactions, it adds on to other interactions, increasing overall contact within a personal community of friends and relatives. Formal social groups also experience increased communication, with heavy Internet use being associated with voluntary organizations and politics. These benefits, however, do accrue to those already well situated and well connected in society, building upon preexisting relationships.

Civic engagement is also enhanced through such online communications. In the planning field, the context for community participation in local decision making extends beyond the local public hearing to Facebook pages, Twitter feeds, and crowd-sourcing citizen perspectives. Crowd sourcing is online problem solving by a large network of people. In local government terms, this allows a broader and sometimes deeper reach into a community for their perspective on a policy issues. The context of community has indeed become integrated into the networked world – consider the flow of Twitter feeds that helped Egypt's 2011 Arab Spring occur. The spread of communications over smart phones enabled the mobilization of resources throughout a protest community leading to a revolution.

Co-morbidity of Mental and Physical Conditions

Kate M Scott, University of Otago, Dunedin, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Mental disorders including mood, anxiety, substance use, and psychotic disorders have been associated with a wide range of physical conditions in both clinical and general population studies. These mental–physical comorbidities can come about either through causal or noncausal mechanisms (shared determinants). Causal mechanisms include a variety of behavioral, biological, psychological, pharmacological, and service delivery pathways through which mental disorders could increase risk of subsequent physical conditions, or physical conditions could increase risk of mental disorders. Shared determinants may include environmental factors, such as childhood adversities, or genetic risk factors. The consequences of mental–physical comorbidity are severe and wide ranging.

Epidemiology of Mental–Physical Comorbidity

Introduction

Mental–physical comorbidity refers to the statistical association of a mental disorder with some kind of medical disease or chronic physical condition, either at a given point of time or within the lifetime of an individual. This association indicates that the two types of disorder (mental and physical) are co-occurring to a degree that is greater than would be expected by chance. Many studies measure mental–physical comorbidity in cross-sectional designs, detecting associations between mental disorder and physical condition prevalences within the same time period (such as the past 1–12 months). This approach documents the association but leaves it unclear whether one disorder influenced the onset of the other in a causal manner (and if so, which came first), or whether both developed at the same time, possibly caused by some other causal factor or factors common to both of them. Prospective studies examine sequential or longitudinal comorbidity, documenting a specific temporal sequence in the association of a disorder, such as depression, with the subsequent incidence of another, such as heart disease, years or decades later. At the population level, the burden of mental–physical comorbidity is considerable. At any age, the majority of those with a mental disorder experience some kind of comorbid chronic physical condition (Scott et al., 2008). In the following sections, the types of medical comorbidities that tend to co-occur with mental disorders are described, the various mechanisms underlying mental–physical comorbidity are discussed, and finally the impact of mental comorbidity is outlined.

Mental–Physical Comorbidities

Numerous studies, both cross-sectional and prospective, have established that depression is associated with a wide range of medical comorbidities such as diabetes, cardiovascular diseases, respiratory diseases, and a range of chronic pain conditions (Evans et al., 2005; Prince et al., 2007). Much of the research in this area involved clinical or primary care samples, but recent data from the World Mental Health surveys have confirmed these associations in general populations around the world (Scott et al., 2007).

Although more attention has been focused on depression, cross-sectional general population studies suggest that anxiety disorders show a similar pattern of concurrent comorbidity with a wide range of physical conditions (Von Korff et al., 2009). In prospective studies, anxiety is often studied with symptom screening scales that do not allow determination of which anxiety disorders might be implicated in which physical conditions. More research is required using clinical diagnoses of anxiety disorders to get a clearer picture of whether some anxiety disorders have specific links with particular physical conditions. The available research indicates that post-traumatic stress disorder (PTSD) is associated with a number of physical comorbidities, and that PTSD and panic disorder may have specific links with coronary heart disease. Panic disorder has also been linked in several studies to respiratory diseases such as asthma or chronic obstructive pulmonary disease (Vögele and Von Leupoldt, 2008).

Alcohol and other drugs have systemic biological effects (Brick, 2004). When these drugs are used with the frequency and duration that characterize substance use disorders, the medical consequences can be profound, ranging from the slow and insidious to acute and life threatening, depending on the drug in question and the dose.

Bipolar disorder and schizophrenia are associated with increased prevalence of a similar range of illnesses, in particular cardiovascular diseases, metabolic diseases, thyroid disease, respiratory disease, hepatitis C, and osteoporosis (Kilbourne et al., 2004; Lambert et al., 2003).

How Mental and Physical Disorders Come to Be Comorbid

There are many mechanisms that have been discussed that could contribute to the overlap of mental and physical conditions. These can be conceptually organized into two overarching models (Scott, 2009; Steptoe, 2007b). The first of these is the causal model. In this model, one condition increases the risk of the other, operating through mechanisms that lead from mental disorder to physical condition (Section From Mental Disorder to Physical Disease), or from physical condition to mental disorder (Section From Physical Disease to Mental

 http://dx.doi.org/10.1016/B978-0-08-097086-8.14147-9

Disorder). The other overarching model is the noncausal or indirect model. This refers to the possibility that there are shared determinants that increase the risk of both mental and physical disorders (Section Shared Determinants). In this model, the comorbidity comes about through these underlying shared risk factors, rather than through either the mental disorder causing the physical condition or vice versa.

From Mental Disorder to Physical Disease

There is now a great deal of evidence from more than 30 prospective studies that depression is associated with subsequent coronary heart disease incidence or occurrence of fatal or nonfatal heart attack (Goldston and Baillie, 2008). Anxiety, also, has been linked prospectively with subsequent heart disease and heart attacks. Several studies have also documented prospective associations of depression and/or anxiety with the onset of type 2 diabetes, stroke, peptic ulcer, chronic pain, and other physical conditions. Research has also shown that most of the medical comorbidities of bipolar disorder and schizophrenia arise following the mental disorder onset.

There have been many biological mechanisms proposed to account for these associations. A number of these mechanisms relate to the functioning of the physiological systems for responding to stress: the autonomic nervous system (through the sympathetic–adrenal–medullary (SAM) axis) and the neuroendocrine system (through the hypothalamic–pituitary–adrenocortical (HPA) axis). Dysregulation of both of these systems has been associated with depression and anxiety disorders (Stetler and Miller, 2011; Young et al., 2004). Dysregulation of the HPA and SAM axes has a range of adverse metabolic, cardiovascular, immune, and neurological effects. These include elevated blood glucose levels, insulin resistance and obesity, enhanced blood clotting, increased blood pressure and reduced heart rate variability, immunosuppression and increased inflammatory response, and a cascade of other effects that contribute to atherosclerosis (Miller et al., 2002; Chrousos and Kino, 2007). So, one main pathway through which depression and anxiety could be affecting subsequent physical health is through the chronic disturbances in stress physiology associated with these mental disorders.

Mental disorders can also affect physical disease risks through behavioral pathways. All mental disorders have a well-established relationship with behavioral risk factors for chronic diseases such as smoking, poor diet, sedentary behavior, and excessive alcohol consumption (Prince et al., 2007). Mental disorders also increase the risk of later onset of physical disease by affecting adherence to treatment of risk factors for specific diseases, whether that treatment involves behavior modification (e.g., smoking cessation, weight reduction, exercise, dietary change) or adherence to medication (e.g., cholesterol-lowering medication). Substance use disorders as well as depression can lead to reduced likelihood of adopting disease prevention measures, increasing risk of contracting as well as transmitting sexually transmitted and other infectious diseases.

An important contribution to the increased risk of physical comorbidities among people with mental disorders is the tendency for physical conditions to be less likely to be detected and treated in people with mental health problems. This may result from a mixture of factors, including the separate delivery of mental from other medical services in most countries. This is not optimal for the recognition and treatment of mental–physical comorbidity. Research among mental health professionals has identified barriers such as lack of explicit allocation of responsibility for medical treatment, lack of service delivery integration, and pessimistic attitudes among treatment providers as to whether improved physical health is possible, or a priority, among those with mental illness (Hyland et al., 2003). There are also treatment barriers that result from the mental disorder itself. The specific phobias involving medical fears, for example, can interfere with dental and medical treatment seeking and so elevate the risk of poor health subsequently. Another example is the cognitive impairment associated with schizophrenia that can interfere with the detection of physical health problems and communication of these to health care providers.

Finally, psychotropic medications underpin some medical comorbidities. This is particularly the case for bipolar and psychotic disorders where the antipsychotic medications prescribed for these disorders can dramatically increase the risk of obesity and metabolic syndrome. These medications can also increase risk for other medical diseases including osteoporosis and cardiovascular disease (Lambert et al., 2003).

From Physical Disease to Mental Disorder

It is intuitive that having a physical disease or chronic condition could, under some circumstances, become depressing or anxiety provoking, and hence increase the likelihood of the development of a comorbid mental disorder. Chronic physical conditions are associated with many difficulties such as disability and functional impairments, chronic pain, disfigurement, stressful medical procedures, challenging lifestyle changes, changes to social networks and intimate relationships, increasing dependency, and sometimes the prospect of a foreshortened future. Many of these difficult consequences of physical illness have been linked to the development of depression in prospective studies (Ormel et al., 1997; Steptoe, 2007a). This is not to suggest that the majority of people with chronic physical conditions develop depression or mental disorders – in fact only a minority do. Whether someone with a physical condition develops a comorbid mental disorder is related not only to the severity and consequences of the physical condition, but also to the individual's beliefs about the illness, its significance in their lives, and their perceived capacity to cope with it (Sharpe and Curran, 2006).

Physical diseases can also result in mental health symptoms or mental disorders mediated by biological disease processes. One example of this is poststroke depression, the likelihood of which has been found to vary depending on stroke laterality and location, suggesting the involvement of neuroanatomical and neurobiological processes (Gaete and Bogousslavsky, 2008). The inflammatory response in the brain following ischemic injury, for example, may lead to serotonin depletion in parts of the brain involved in emotional regulation. These biological changes following stroke may work alongside or interact with the psychological losses and disability associated with stroke to increase depression risk. A related area of research is on vascular depression as a specific subtype of depression in the elderly resulting from microvascular lesions

in the brain (Baldwin, 2005). The depression following Parkinson's disease may also be a biological consequence of underlying neurodegeneration; although as with stroke, the psychological effects of Parkinson's may be a contributing factor. Diseases such as cancer and HIV/AIDS are further examples of where the episodes of depression that frequently follow the disease diagnosis may result from an intertwining of biological and psychological factors.

A third pathway from physical disease to mental disorder is via medications prescribed for the physical condition. A number of cardiovascular medications have been suggested to increase depression risk (Shah et al., 2011; Licht et al., 2010), although this is methodologically challenging to determine and further research is needed. Treatment with interferon, which is used in a variety of diseases including some cancers, multiple sclerosis, and hepatitis C, is widely reputed to increase the risk of depression. Several other medications have also been implicated in depression and also other mental health problems. Efavirenz, for example, a commonly used nonnucleoside reverse transcriptase inhibitor frequently prescribed in combination with other antiretroviral regimens (e.g., protease inhibitors) for the treatment of HIV has been associated with behaviors such as suicidal ideation, aggressive/impulsive behavior, paranoid reactions, and manic reactions (Sütterlin et al., 2010) Nevertheless, reviews of this area have concluded that medically induced depressions are symptomatically different from typical major depressive disorder (Patten and Barbui, 2004).

Barriers also exist in detecting and treating mental disorders among those with physical conditions (Evans et al., 2005). Although this does not cause the comorbidity, it prolongs it, increasing the prevalence of mental–physical comorbidity observed in research studies (see also Section Consequences and Implications of Mental–Physical Comorbidity).

Shared Determinants

The shared determinants model refers to the fact that mental disorders and chronic physical conditions have some risk factors in common. This raises the possibility that their comorbidity could be a function of this shared etiology rather than a causal connection. One such shared etiological factor is poor fetal growth (manifesting as low birth weight for gestational age). This has been found to predict adult-onset cardiovascular disease, metabolic syndrome and type 2 diabetes, obesity, hypertension, and osteoporosis (Barker et al., 2002), as well as adolescent- and adult-onset depression (Thompson et al., 2001). One of the hypothesized mechanisms for these connections has been the influence of gestational stress on HPA axis settings.

Animal studies (Sanchez, 2006) and clinical studies in humans (Heim et al., 2000) indicate that reactivity to stress can be heightened not only prenatally, but also in early life by adverse maternal care or other early life adversities. As well as this laboratory research, there are also epidemiological studies linking childhood adversities such as abuse and neglect with later mental (Gilbert et al., 2009) and physical ill-health (Wegman and Stetler, 2009). This body of research has focused attention on childhood adversities as possible shared determinants of mental–physical comorbidity (Scott, 2009). Preliminary exploration of this possibility using retrospective data from the World Mental Health Surveys found that childhood adversities explained some of the association of mental disorders with subsequent onset of physical conditions (Scott et al., 2011), but not all. Some mental–physical comorbidities could have other environmental and/or genetic factors in common.

Consequences and Implications of Mental–Physical Comorbidity

The most severe consequence of mental–physical comorbidity is premature mortality. People with mental disorders, especially depression and schizophrenia, have increased mortality when compared with people without those conditions, even after statistically controlling for the effect of suicide (Harris and Barraclough, 1998) (Prince et al., 2007). Research also shows that comorbid mental disorders are associated with increased morbidity among people with a range of chronic physical conditions including arthritis, coronary heart disease, stroke, and diabetes (Von Korff, 2009). There have been many studies elucidating the reasons behind this effect of comorbid depression on worsening the prognosis of physical disease. Co-occurring mental disorders such as depression and anxiety increase the numbers of physical symptoms experienced in diseases such as diabetes and asthma, even after adjusting for medical severity. They are also known to amplify the experience of physical symptoms, whether medically explained or not. Mental disorders prolong and worsen the clinical course of physical conditions, in part by interfering with self-management of chronic conditions and treatment adherence. As one example, many studies have found that both depression and anxiety lead to poorer glycemic control in diabetes and reduced likelihood of maintaining dietary and physical activity changes. Similar findings have been observed for cardiovascular diseases. Quality of life is therefore greatly affected by co-occurring mental disorders, and functional disability is also amplified.

This body of research highlighting the deleterious effects of mental disorders on medical disease and chronic physical condition outcomes, together with the evidence of higher health care costs associated with comorbid depression, has motivated intervention trials of depression treatment in medical patients. Unfortunately the trials conducted to date in heart disease and diabetes have found few, if any, positive effects on medical outcomes (The ENRICHD Investigators, 2003; Katon et al., 2004). There could be a number of reasons for this, but one of them may be that the depression treatment in these trials is undertaken too late in the life course. Most people who have a depressive episode later in life (e.g., comorbid with a physical condition) have had a prior episode of depression, anxiety, or some other mental disorder earlier in life. As discussed above, depression and other mental disorders may be influencing physical health through biological, behavioral, and pharmacological pathways for many years prior to the clinical symptoms of the medical disease becoming manifest. This suggests that more rigorous and systematic detection and treatment of mental disorders in adolescence and early adulthood, coupled with careful monitoring of physical health in those with chronic mental disorders, has the potential

to greatly enhance mental and physical health throughout the life course.

Comparative Evolutionary Psychology: Current Status and a Proposal for a More Integrated Future

Jennifer Vonk and Todd K Shackelford, Oakland University, Rochester, MI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Taking into account the shortcomings and strengths of the related fields of comparative psychology and evolutionary psychology, we propose merging these subfields into Comparative Evolutionary Psychology. This new field will encompass the study of cognitive continuities and discontinuities across species, with the goal of understanding both ultimate and proximal causes for the emergence of various traits. Importantly, comparative evolutionary psychologists will embrace both field and laboratory approaches and shed the shackles of an exclusive focus on uniquely human traits. This new field will exemplify an appreciation for a diversity of traits in both closely related and distantly related species that an understanding of evolution demands.

Defining Terms

Every field of scientific inquiry has its problems. The subdisciplines within psychology are no exception. Perhaps one of the greatest stumbling blocks to progress is the perceived need of psychologists to self-identify as belonging to one particular area within psychology to the exclusion of others. This need is, at its foundation, antithetical to an integrative science and to interdisciplinary work. We see this problem expressed in the long-standing debate about what it is to be a comparative psychologist or an evolutionary psychologist, perhaps most exhaustively examined in a special issue of the *Journal of Comparative Psychology* published over two decades ago (Burghardt, in press). Papini (2003) suggested that the field of comparative psychology should focus on the phylogenetic history and adaptive significance as well as the ontogenetic origins of an organism's behavior. Cartwright (2000) suggested that comparative psychologists failed to bridge the divide between human and nonhuman, more successfully bridged by ecologists and sociobiologists. Evolutionary psychology has built upon these fields by focusing on the investigation of psychological mechanisms as adaptations produced by natural or sexual selection to solve the problems faced in our ancestral history. The focus of evolutionary psychology is thus on the ultimate cause of human behaviors and characteristics. Evolutionary psychology represents an integrated set of hypotheses focused on selection, modularity, and adaptation, and is particularly interested in applying evolutionary principles to the mind (Pinker, 1999; *see* Evolution of Cognition: An Adaptationist Perspective). Evolutionary psychology is linked more strongly to sociobiology and the biological sciences, in general, and to cognitive psychology and behavioral genetics, as well (*see* Sociobiology: Overview). Comparative psychology is tightly linked to primatology, behaviorism, ethology, and, often, cognitive science. There have been various proposals to unite the two fields (most recently, Vonk and Shackelford, 2012). Vonk and Shackelford (2012) focused on specific problems within each field and attempted to identify barriers to a more open foray into something akin to cognitive behavioral ethological psychology with a focus on studying evolved traits in a wide range of species. Our proposal, which we elaborate upon here, is to unite these areas of research into Comparative Evolutionary Psychology, with the goal of removing barriers between (1) those who work in the field and those who work in the laboratory, (2) those who work with different species with a nomothetic or ideographic approach, and, especially, (3) those with a human-centered perspective and those who study individual species that are of interest in their own right.

Goals and Limitations

Comparative Psychology: Focus on Continuity

We believe that both comparative psychologists and evolutionary psychologists have sometimes fallen into the trap of endorsing goals that are both narrowly focused and ultimately stand in defiance of evolutionary theory. For instance, we focused on the tendency of comparative psychologists to focus on continuity and similarity between species, to the neglect of equally interesting differences and species' unique adaptations (Vonk and Shackelford, 2012; *see* Comparative Method in Evolutionary Studies). Although we applaud recent efforts to expand the species of study and the questions and topics under investigation, we suggest that much would be gained by returning to the lessons of methodological behaviorists and logical positivists, who fought to place psychology among the sciences. We see the trend in animal research, particularly with regard to cognitive research, as highlighting similarities with human traits and abilities, but at the expense of objectivity. That is, the focus has been on cognitive continuity, and equally interesting discontinuities have sometimes been discounted in favor of arguing for contexts that may have interfered with the ability to express humanlike traits (Girndt et al., 2008; Vonk and Povinelli, 2006). Sometimes alternative outcomes are obtained and researchers still hold steadfast to 'preferred' hypotheses that center on similarities between humans and their closest relatives, rather than giving equal weight to equally plausible, or even more plausible, alternative explanations for their findings. As just one recent example, in a recent study of tool use in apes, Herrmann et al. (2008, p. 229) write: "Although our results show that apes

 http://dx.doi.org/10.1016/B978-0-08-097086-8.81015-6

succeeded in some problems spontaneously, their group performance never exceeded 70% in the initial six trials. It is true that with additional trials performance increased, but it still remained quite low in most conditions. One possible explanation for this outcome is that their performance is not based on causal knowledge about the task. Another possibility is that they possess some causal knowledge, but that certain task features make it hard to express it consistently." These authors insist that the apes have knowledge even when that knowledge is not clearly demonstrated in the tasks at hand rather than allowing the data to speak for itself and relinquishing their preferred hypothesis to accept a more conservative conclusion that perhaps the apes do not possess causal knowledge at all, and instead show the ability to learn by trial and error or reason about observable features.

This approach of seeking evidence for humanlike traits in nonhuman species has sometimes been deemed the 'Holy Grail' approach to comparative psychology (Povinelli and Vonk, 2004). We propose that, instead, investigators focus on traits that are expressed within a species' ecological and social environments and examine factors that may have led to the expression of these traits. Such an approach need not exclude laboratory studies that seek to explore the generalizability of behaviors to novel contexts under controlled conditions. Further, studying both captive and wild animals has the potential to illuminate the role of ontogenetic factors and the role of plasticity in development. This is not a novel argument, but when combined with a broadly comparative perspective and an evolutionary framework, this approach has the potential to unify the study of comparative psychology and evolutionary psychology in a manner that has clearly not been accomplished in recent years. The fact that this unification has not yet been achieved is evidenced by the recent number of proposals seeking greater integration. Along with our own volume (Vonk and Shackelford, 2012), see also special issues of *Philosophical Transactions of the Royal Proceedings B*, edited by Grodzinski, Clayton, and Thornton (2012) and Heyes and Frith (2012) focusing on the evolution of the animal and human mind, respectively.

Researchers should certainly be encouraged to consider whether existing capacities are similar to or different from those in both closely related and distantly related species. It is precisely such considerations that allow us to speculate about the evolutionary forces behind the emergence of these traits. However, we suggest that researchers should not be motivated by the desire to seek evidence for particular patterns of behavior simply because those behaviors exist in humans (Shettleworth, 2007), particularly if there is no ecologically relevant reason to find such a trait in the species in question. We should examine behaviors and abilities that the animal exhibits in its natural environment rather than design tasks with a predetermined goal or 'stack the deck' to find evidence for traits that have not yet appeared in natural environments. For instance, research should be motivated by an interest in adding to our understanding of capacities in species with particular behavioral ecologies, rather than attempting to demonstrate how 'intelligent' a particular species is. Thus, explorations of differences in spatial memory as a function of whether species cache food or must find patchily distributed food resources over large ranges are particularly fruitful (Shettleworth, 2010). Perdue et al.'s (2011) recent examination of sex differences in carnivore search strategies as a function of mating strategies and range size is another excellent example of such research. An unbiased approach is more likely to illuminate both parallel and convergent evolutionary processes.

The allure of Holy Grail pursuits (Povinelli and Vonk, 2004) has attracted many researchers. Rather than designing experimental tasks to uncover the cognitive capacities of a species with consideration of the ecological and social forces likely to have given rise to particular traits in particular populations, some researchers seem especially focused on seeking evidence for humanlike abilities in nonhumans, regardless of that species' ecological niche or phylogenetic distance from humans. This anthropocentric focus can be seen in book titles such as *Kanzi: The Ape at the Brink of the Human Mind* (Savage-Rumbaugh and Lewin, 1994), *Next of Kin* (Fouts and Mills, 1997), *Our Inner Ape* (de Waal, 2005), *Chimpanzee Politics* (de Waal, 1982), and *The Smartest Animals on the Planet* (Boysen & Custance, 2009). Although humans are naturally drawn to species that share certain humanlike characteristics such as the ability to read human social cues, the role of the scientist should be to laud other equally impressive abilities that various species have evolved to solve problems in their unique physical and social environments. Together, comparative evolutionary psychologists are best equipped to do so.

Evolutionary Psychology: Focus on Human Uniqueness

Some evolutionary psychologists have been similarly focused on the traits that define what it is to be human, such as cooperation and prosocial behavior (Fehr et al., 2002; Fehr and Fischbacher, 2004; Fehr and Gintis, 2007). Such a focus may result in a reversal of the Holy Grail pursuits by comparative psychologists in that researchers may focus on traits that they assume are not shared with other species, in the absence of evidence for these assumptions (Matsuzawa, 2012; Saxe, 2006; Tomasello, 1998). In actuality, evolutionary psychologists are poised to demonstrate continuities, with much work focused on sex differences in mating strategies that closely parallel sex differences in other species (Birkhead et al., 1987; Buss, 1995; Buunk et al., 1996; Schmitt, 2005; *see* Human Mate Choice, Evolution of). However, this work has been historically controversial within psychology. If psychologists were concerned with identifying both similarities and differences across broad taxonomic groups, with the goal of elucidating rather than assuming the cross-species links, comparative psychology and evolutionary psychology may find themselves less under attack and more often in the driver's seat when it comes to unifying the subfields within psychology.

Diverse Topics: The Need for Evolutionary Framework

On a positive note, examples of recent research abound with forays into previously discouraged topics for comparative research, such as consciousness and metacognition. Not only are such topics fervently studied nowadays, but their study is no longer restricted to primates; they have been extended to species as evolutionarily distant from humans as cephalopods (Mather, 2008), pigeons (Sutton and Shettleworth, 2008), and

rats (Foote and Crystal, 2007). However, seldom are such examples couched in terms of why such abilities might exist in such distantly related species. Even when such attempts are made, they seem like post hoc justifications for the research. For example, why should elephants exhibit mirror self-recognition (Plotnik et al., 2006)? Elephants live in relatively large and complex social groups and display extraordinary memory, but so do most canine species, and birds such as psittacines and corvids, and there is no evidence as of yet for mirror self-recognition in these latter species (although see Prior et al., 2008). One cannot simply suggest that a single factor, such as developing within a complex social environment, may have given rise to any particular 'higher order' cognitive trait, such as mirror self-recognition, without a logical exposition of why that factor would have led to the emergence of that particular trait, and why in this species or this population and not in others that share this factor. We would hope to encounter discussions of parallel or convergent evolutionary processes focused on life in complex social groups, or challenging physical environments necessitating the need for advanced causal reasoning to extract food, not as a post hoc suggestion, but as a driving impetus to conduct the research with multiple species and populations to begin with. In fact, one of us has recently been motivated to explore the cognitive abilities of a large-brained relatively nonsocial mammal with a nod to the importance of testing the 'social intelligence' hypothesis in nonsocial species (Vonk and Beran, 2012; Vonk et al., 2012). The social intelligence hypothesis (Humphrey, 1976; Jolly, 1966) states that species that have evolved to live in large, complex social groups will display superior social cognitive abilities (and perhaps more sophisticated cognition, in general) relative to less social species. Thus, we need to test this hypothesis by comparing social and nonsocial species that are otherwise similar (such as comparing lions with tigers or bears with wild dogs). We have also recently embarked upon a program of research to compare the cognitive abilities of various species of bats that differ both in sociality and in diet. All too often research seems instead to proceed more like a traditional Mardi Gras hunt – a search for all of the random ingredients to make a great gumbo. Once some piecemeal evidence for humanlike capacities in other species is uncovered, an exciting story is then woven together and submitted for publication in a high-profile journal where it will likely attract much publicity. This approach may tell us more about our own biases than about the minds or capacities of the species we so painstakingly study (Povinelli and Vonk, 2004; Shettleworth, 2007).

Biases: False Dichotomies

A biased approach is problematic for several reasons, not just because it flies in the face of the scientific process, but also because it may set the researcher up to fail. Creating scenarios in which the desired outcome must be an all-or-none result ignores the possibility of discovering many other results. Scientific reasoning should encourage researchers to acknowledge possible outcomes that they may not anticipate. When we do not leave ourselves open to such discoveries we may not discover them. If the only options we were open to interpreting consisted of 'humanlike'/'nonhumanlike,' we would miss out on 'chimpanzee-like' or 'elephant-like' behaviors and cognitions that we may not have imagined prior to our investigation. Before Povinelli (2012) began his extensive study of chimpanzees' understanding of weight, we may not have anticipated that the chimpanzee concept of weight was so tied to kinesthetic impressions on the body and so removed from the objects that they were lifting. The studies discussed by Povinelli (2012) demonstrate an attempt to understand how chimpanzees perceive weight – not just whether it maps onto the human concept of weight. Admittedly, it is more difficult to work from a nonanthropocentric frame as it may not be possible to experience the world through a sensory system we do not ourselves embody.

Approaching research with the idea that results will pivot on a false dichotomy such as humanlike/non humanlike, innate/learned, or conscious/automatic is bound to lead to pressure to interpret results in line with a particular strong viewpoint, when plausible alternatives might exist. The difficulty in publishing 'null' results has likely contributed to such a drive in our field. Scientists are rewarded by the public's enthusiasm for demonstrations of humanlike behaviors in even distantly related species. When rooks were discovered to drop rocks in water to raise the water levels so that they could retrieve previously inaccessible worms (Bird and Emery, 2009), the findings were touted as evidence for causal reasoning and insight, even 'tool use' – something that was once attributed only to humans. Thus, the results garnered much attention both in the scientific community and in the public. The same was true when Betty, a new Caledonian crow, another member of the corvid family, was seen to bend a piece of straight wire into a hook to retrieve a food reward from the bottom of a pipe (Weir et al., 2002), even though birds presumably bend wires and similar objects naturally when nest building. Betty may have arrived accidently at the solution to the task at hand, rather than by cognitive insight. If the birds were never to modify the objects, or use the tools at all, the results would likely not be published, or relegated to a lower impact journal, and would not garner any excitement either within or outside of the research community. Thus, one can see the motivation to seek empirical findings that stress continuity with human traits – particularly those that have been set as benchmarks of human uniqueness. Such traits are dangled like carrots tempting researchers to knock them from that status, just as 'tool use' and 'theory of mind (ToM)' have now forever been wrenched from the fists of Cartesians who would claim a strong divide between man and beast, with animals deemed incapable of any form of thought or feeling.

If there should be any lesson from the Cartesian dichotomy of the past, which allowed for decades of inhumane animal experimentation, it is that we should not create such strong divisions and set up false dichotomies when we design scientific studies. Although we have argued that researchers should not be blinded by desires to seek evidence for continuity in cognitive processes, abandoning equally strong evidence for cognitive discontinuities, it is important to stress that both continuity and discontinuity exist in nature; these complementary processes are together central tenets of evolutionary theory. In our recent volume on Comparative Evolutionary Psychology (Vonk and Shackelford, 2012), we stressed the value of casting aside such dichotomies and divisions between

those approaching research from different perspectives, frameworks, and methodologies. We advocated a release from the lack of objectivity that resonates in Holy Grail pursuits, and we advocated a return to the lessons of the logical positivists and the methodological behaviorists, who stressed the objectivity of the scientific method. We cannot move forward with credibility as a science if we do not do so. We cannot accept theories without extensive tests and we must revise hypotheses when the data do not fit, or are consistent with multiple hypotheses.

When investigators are overly invested in existing theory or preferred hypotheses, however, they sometimes manufacture middle ground hypotheses to satisfy their theoretical framework and fit the data. Thus, one might see researchers arguing that, first, chimpanzees do not share human ToM abilities (Tomasello et al., 1993), then that chimpanzees do share some ToM abilities (Tomasello et al., 2003), later that these abilities might be exhibited only within certain restricted contexts, such as in competitive contexts (Hare, 2001). These types of arguments, although interesting, do not address the very reason ToM is likely to have evolved in the first place – to enable an organism's behavioral flexibility in anticipating another organism's responses in a variety of novel circumstances. If one can reason about another's mental states in only a very constrained set of situations – those that have driven that species' fitness through imposing mating or feeding advantages (i.e., by allowing one to compete for food) – then it seems more likely a mechanism that is innate and inflexible, and precisely not what ToM is designed to do. By maintaining a clear evolutionary perspective, comparative psychologists will be better able to reject implausible hypotheses or explanations that are driven by biases to discover commonalities regardless of evidence for divergence.

The 'Problem' of 'Null' Results

Few people are excited by 'negative' findings or 'null' results, or the absence of humanlike traits in our nonhuman counterparts. The fact that we label the absence of evidence for such abilities as 'negative results' says more about our anthropocentric biases than it says about the value of the results. Such findings can be just as illuminating as 'positive' results. They tell us just as much about the animals' abilities and the way that they reason. Or at least they could, were the tests and experiments properly constructed in such a manner as to highlight what the subjects could do, and how they think, rather than being fashioned in a dichotomous manner: Do they do what humans do, or do they not? In one example, Vonk and Subiaul (2009) explored chimpanzees' ability to reason about humans' capability to perform a simple task – offering a food tray to the ape subjects. The humans' ability was constrained on the basis of whether their arms or legs were visible and available to perform the physical actions required. These results (and other similar findings) are often interpreted as failures on the part of the chimpanzees, because they did not evidence causal reasoning. However, what the researchers showed was that chimpanzees were reasoning – they just were not reasoning about the causally relevant variables in the task – even though those variables were directly observable. However, rather than showing what the chimpanzees could not do, Vonk and Subiaul, in a series of follow-up studies, attempted to show what features of the task the chimpanzees were attending to, and what features allowed them to perform successfully on some trials. And this is the bottom line in many similar studies – chimpanzees (and other animals) may or may not 'succeed' at the tasks we present to them; what matters for illuminating the cognitive processes underlying their performance is how they succeed (or fail) at the tasks. And the same should be said for determining how humans succeed in experimental tasks. We should not take for granted that humans use particular mechanisms for solving problems, until we have tested these hypotheses (Silva et al., 2005, 2008).

A closely related point is that researchers often suggest that chimpanzees 'fail' particular tasks when they do not perform in a manner consistent with how humans might be expected to perform (sometimes in the absence of having any available human data to bear on the issue). Such claims have led to suggestions that captive chimpanzees are unable to perform well in cognitive experiments because they have been cognitively deprived, removed from the socially rich lives they would have led in the wild, without the challenges of finding food, mates and shelter, and navigating social conflicts, forging alliances within large groups, and so on (Boesch, 2008). These arguments neglect the fact that experimentally experienced chimpanzees have a wealth of experiences that wild chimpanzees do not. They also live in social groups. But, in addition to that, they have extensive experience with human caretakers, human-made objects and artifacts, and contrived situations and contingencies that they would not face in the wild. Furthermore, it is precisely when you take an animal out of the environment in which evolution has sculpted them to survive that you can best determine their ability to generalize knowledge to unfamiliar and novel circumstances, as humans often do. Still, these critics also fail to acknowledge that chimpanzees that sometimes do not reach criterion or perfect performance on experimental tasks are not 'failing' our tasks. Rather, they are illuminating for us how the chimpanzee sees the world; and it is often quite different from our human-centered biases have led us to see. It is only through thoughtful probing of their responses in carefully constructed post hoc tests that we are able to learn more about their thoughts. The chimpanzees that have participated in dozens or hundreds of experiments designed by psychologists do not 'fail to be human.' Rather, they succeed at being chimpanzees, and as primatologists and objective scientists, it is our mission to learn what that means. Where results appear to differ between laboratories, it is often not the results that differ, but the interpretation of the results.

We should not claim continuity or discontinuity, or 'high' or 'low' order explanations, for either humans or nonhumans until we have examined alternative explanations for performance in our tests. Only when we fashion our experiments in an unbiased, nonhuman-centered way with an open mind as to how other species might approach problems with a consideration of the sorts of problems, they have evolved to face will we be enlightened as to the kinds of minds with which we share this planet. We will not find a human mind in another species, not even those species most closely related to humans. Those species have evolved their own traits, capacities, and thought

processes – some of which are equally impressive, astounding, and perhaps beyond our capacity to comprehend. We must embrace the nature of evolution – an appreciation for both continuity and discontinuity – even in closely related species such as humans and other great apes. In doing so, we may have to abandon Holy Grail pursuits and be open to finding evidence for abilities that our closest relatives have that we do not, and vice versa. We may also find evidence for humanlike abilities in distantly related species. We need not attempt to turn chimpanzees into some kind of half-human hybrid to appreciate their cognitive accomplishments. Our study of their minds should not be guided by such a missive.

Bridging Gaps

On that note, comparative evolutionary psychologists could take heed from the early ethologists who remained focused on the goals of determining mechanisms underlying both human and nonhuman behaviors at both the ultimate and proximate levels. To their credit, evolutionary psychologists have incorporated advances in cognitive science, behavioral economics, developmental psychology, linguistics, cultural anthropology, sociobiology, and ethology, and yet work from an overarching theoretical framework. The basic mechanisms of natural selection and sexual selection can explain both human and nonhuman mating practices (Buss, 1989, 1994), sex differences in spatial abilities (Voyer, Voyer & Bryden, 1995), attractiveness (Burke and Sulikowski, 2010), investment in offspring (Alvergne et al., 2009), and so on. Comparative psychologists, while unequivocally but sometimes only implicitly accepting evolutionary theory, have not always placed their work within the same overarching framework, and sometimes take esoteric side trips, investigating questions that, although interesting, do little to explain the forces giving rise to various traits in different populations.

This is not to say that comparative psychology is fundamentally flawed relative to evolutionary psychology, or that evolutionary psychology is beyond reproach. We have been critical of the focus of comparative psychologists to seek out commonalities between humans and other species at the expense of exploring many fascinating adaptations that humans do not share (echolocation in distantly related cetaceans and Chiroptera for instance). We have also been critical of evolutionary psychology for its tendency to focus exclusively on what other species can tell us about human evolution. Indeed, we recently attended a talk where an evolutionary psychologist defined evolutionary psychology as the study of human behavior and the human mind. This unitary focus on humans was surprising. There will be those who will staunchly defend their fields against such criticisms and point to the many counterexamples that defy our critiques. For example, there are researchers studying mate guarding in birds (Birkhead, 1988) that parallels work in humans. This work may be less prototypical of either comparative or evolutionary psychology. Should it be labeled as one or the other? Or should such work fall under the umbrella of Comparative Evolutionary Psychology, as it is both comparative in its nature and evolutionary in its focus? We would say yes – that is, exactly the kind of work that this new field would embrace. But the results of such investigations will shed light not only on human psychology but also on reasons for the emergence of this behavior in other species.

Although both comparative psychologists and evolutionary psychologists are interested in the mechanisms underlying behaviors exhibited by various species and specific human and nonhuman populations, as well as the evolutionary forces that gave rise to such traits and behaviors, these two fields have taken somewhat disparate trajectories, rather than culminating in a single field of study. We propose that much would be gained if the fields were merged into a new science of Comparative Evolutionary Psychology. The goals would remain – the new science would aim to explore the ultimate and proximate causes of behavior in humans and their close and distant relatives – and the relatively newfound appreciation for an eclectic approach to empirical questions and methodologies would be retained. We must adopt more open-minded approaches to our studies, in which we do not grasp firmly onto 'preferred hypotheses,' but are willing to formulate new theories and hypotheses that emerge from a consideration of the contexts that shape an animal's evolutionary history.

One of the solutions to removing these barriers is to increase communication and advocate for collaborations among researchers with different perspectives and specialized expertise. In order to best accomplish this open-minded perspective, we suggest dissembling the barriers that arose when creating false dichotomies between nature/nurture, behaviorism/nativism, field/laboratory, ideographic/nomothetic, and human/nonhuman research, and, most importantly, a willingness to let go of the idea that other species are most valuable when they most closely approximate humans (cf. Savage-Rumbaugh and Lewin, 1994). By doing so, we will allow ourselves to appreciate the diversity that exists on this planet, and to better understand the process of evolution – as it applies to both the behavior and psychology of organisms. Thus Comparative Evolutionary Psychology can be a single unified field for the study of evolved traits in all species.

Abstract

Comparative health systems research examines the similarities and differences between and among health policies, practices, institutions, and outcomes in different countries in order to examine the effects of health reforms, the ways in which international initiatives are adapted to suit local needs and interests, and the strategies different health systems use to deal with the same problems. This article provides a discussion of the comparative study of health systems – the limitations and benefits of this form of analysis, a review of some of the current issues researchers are engaged in, and two brief case studies.

Introduction

Efficiency? Cost-savings? Coverage? Participation? What can be more confusing than talking about health systems, except perhaps trying to compare them to each other? Which system is 'best', and what is 'best', and who defines 'best'? Should the comparison of different health systems focus on financing and spending, health system reform, the role of practitioners, the role of patients and the public, and/or technological innovation? This article provides a discussion of the comparative study of health systems – the limitations and benefits of this form of analysis, a review of some of the current issues researchers are engaged in, and then provides two brief case studies, and some concluding thoughts.

Cross-national comparative research explores the similarities and differences between/among health policies, programs, institutions, and outcomes in different countries with the aim of drawing conclusions about potential advantages/disadvantages (Johnson and Stoskopf, 2010). It often seeks to examine the effects of regional health reforms or the ways in which international initiatives are adapted to suit local needs and interests (Blank and Burau, 2007). Furthermore, it can lead to shared 'lessons learned' by pointing to the strategies different health systems use to deal with the same problems, the obstacles they faced, the solutions that were put in practice, and the kinds of outcomes generated (Gonzalez Block, 1997).

We begin with an overview of comparative health systems (CHS) research. That leads us to a discussion of current controversies and concerns in CHS research, for instance, the roles of privatization, decentralization, the participation of nongovernmental organizations (NGOs) in healthcare, and the function of patient and public involvement (PPI). In order to investigate one of these concerns – the role of PPI – we provide two case studies from very distinct health systems in Latin America (Cuba and Argentina). We conclude the article with new questions for the readers to consider.

Overview of CHS

The focus and methods used in CHS research have changed in relation to the approaches used during particular times. Initially methods relied on quantitative data derived from secondary sources and focused on macrolevel analysis that formed the preferred approach for carrying out CHS analyses (Gauld, 2005: p. 11). However, after several authors identified the limitations of this approach (Mechanic and Rochefort, 1996; Whiteford and Nixon, 1999), more recent studies have shown an interest in in-depth analyses using a mixed methods design or focusing solely on qualitative data to provide case studies of health systems in different locales (Atkinson et al., 2000; Bossert, 1998; Dawad and Veenstra, 2007; Gilson et al., 2001).

Contextualization has come to be recognized as an intrinsic component of comparative research as it provides an insight into knowledge absent from strictly quantitative analyses (Carmel, 1999) and is able to "reconcile complexity, detail and context" (Mangen, 1999: p. 110). This kind of context-sensitive approach has been proposed by Wrede et al. where comparisons are made at the mesolevel to "make connections between policy and practice in different welfare regimes" (2006: p. 2987). This approach can lead to an analysis capable of clarifying the practices of care (key actors involved, negotiation of institutional structures, historical processes, etc.) and not just the outcomes (Wrede et al., 2006: p. 2989). Even though debates about the best way to carry out CHS research continue, numerous publications concur that there are evident benefits to implementing this type of research despite its limitations (see **Table 1**).

Issues in CHS

Decentralization

Decentralization has been defined as a process "involving a variety of mechanisms to transfer fiscal, administrative, ownership and/or political authority for health service delivery from the central Ministry of Health (MoH) to alternative institutions" (Bossert and Beauvais, 2002: p. 14). This transfer of authority is envisioned as producing health systems capable of adapting to local contexts and the requirements of the local population, thus becoming more effective (in terms of outcomes and costs), accessible, and equitable (Bossert and Beauvais, 2002: p. 14). Previous studies using a CHS approach have shed light on the challenges associated with implementing decentralization strategies and the important role played by the local context in the

Table 1 Summary of the benefits and limitations of CHS research

Benefits
Identify cases of best practices and failures worldwide with the intent to improve healthcare delivery
Show global trends in health policies and systems and outline examples of convergence and social embeddedness
Investigate how healthcare systems impact health status
Shed light on the role the local context plays in the shaping of international policies and programs
Strengthen cross-country research capacity
Point to the processes behind the development of particular health systems
Inform future policy direction
Limitations
Ignores the variations and complexity within health systems and countries
The typologies of health systems are not always matched with the study objectives
Lack of a standard definition of 'health system' and its components
Difficulties applying the same analytical concepts cross-culturally
Difficulties obtaining or accessing the same type of data in different countries to make comparisons
Lack of funding for carrying out comparative research across numerous countries

Decentred comparative research: context sensitive analysis of maternal health care. Social Science & Medicine 63, 2986–2997.

shaping of international policies (Bossert and Beauvais, 2002). They have concluded that one size fits all models seldom result in positive changes at the local level, and thus, decentralization strategies must be developed in accordance with the characteristics of each political, economic, and cultural context.

Health Financing and Expenditure

There has been a worldwide trend to increase the spending on health services (Mechanic and Rochefort, 1996: p. 244), but with economic crises, governments are finding it difficult to provide good-quality healthcare to a changing and expanding population in a context of scarce resources (Ruggie, 2001: p. 6543). As the percentage of GDP allocated to covering healthcare costs increases (particularly in developed countries) (Johnson and Stoskopf, 2010), researchers have explored issues linked to cost-containment and effectiveness (Whiteford and Nixon, 1999). CHS research has slowly abandoned studies with a narrow view of the economic performance of health systems which focused mainly on inputs and outputs and neglected the wide range of factors that affect the use of health resources. Instead, more complex research designs capable of considering multidimensional social, political, and cultural factors that affect economic efficiency are becoming more common (Whiteford and Nixon, 1999).

The Role of NGOs

NGOs in the form of grassroots movements, health NGOs (such as Partners in Health, and Medicines sans Frontieres), and transnational governmental organizations such as the World Health Organization (WHO) and Pan American Health Organization (PAHO) have greatly influenced the way healthcare is delivered worldwide (Walker et al., 2010). These organizations currently influence international policy decisions, run health educational and prevention campaigns, and provide health services in instances where the public health system does not have enough resources, cannot reach marginalized and isolated populations, or is dealing with a temporary crisis (e.g., an epidemic outbreak or a natural disaster) (Schuller, 2007, 2010; Pfeiffer, 2003). In many instances, they have become *de facto* health systems as aid organizations increasingly turn to NGOs to provide healthcare and funnel their resources through them (Pfeiffer, 2004).

Changing Demographics and Emerging and Re-Emerging Diseases

The effects of an aging population are being felt across many parts of the globe. Johnson and Stoskopf have identified these as: "(1) increasing healthcare costs/fewer young people to spread the risk, (2) an inability to replace the elderly in the workforce, (3) inadequate planning for long-term solutions/facilities, (4) how to finance health care and pensions, and (5) end-of-life costs" (2010: p. 408). This demographic change has direct effects on the types of services that must be made available to the population (mainly focusing on the management of chronic diseases and end-of-life care), as well as the programs of care outside of the health system that need to be put in place (Johnson and Stoskopf, 2010: p. 408).

Other recent challenges faced by health systems worldwide are emerging diseases such as obesity or re-emerging diseases such as multidrug-resistant tuberculosis. In 2008, it was estimated that over 1.4 billion adults older than 20 were overweight and over 40 million children younger than 5 were overweight in 2011 (WHO, 2013). Obesity in childhood raises the probability of developing chronic conditions such as type 2 diabetes, heart disease, hypertension, and some forms of cancer which require frequent medical attention and monitoring (Blank and Burau, 2007: p. 202). The increase in the international flows of people, the deterioration of living conditions and overcrowding, severe climate change, and the overuse of antibiotics have contributed to the emergence of new infectious diseases (SARS, avian influenza, and H1N1) and reemergence of previously eradicated ones (Johnson and Stoskopf, 2010: pp. 35–36). These diseases represent new challenges for already burdened health systems. Furthermore, as global epidemics become more common, health systems must become globalized in their conceptualization and treatment of disease (Armelagos and Harper, 2005).

Community Participation in Health

The process of enhancing the participation of the general public in healthcare is complex and has received multiple definitions. In some parts of the world, it is referred to as community

participation or involvement, while in other places, labels such as PPI, service user involvement, or users with active participation are more common (Belmartino and Bloch, 1984; Mockford et al., 2012; Reyes Álvarez et al., 1996; Solitario et al., 2008). Since the Declaration of Alma-Ata which established that "the people have the right and duty to participate individually and collectively in the planning and implementation of their health care", organizations such as the WHO, UNICEF, and PAHO have led international initiatives to promote community participation in health (WHO, 1999).

The main reasons for promoting public participation in healthcare, among others, are to increase accountability by creating more transparent decision-making processes, to challenge health inequities, to ensure the services provided are relevant to the population and adaptable to their changing needs, to maintain communication channels between health authorities and the general public, and to establish a sense of commitment and responsibility in the general public regarding health (Litva et al., 2002; Sang, 2004; Staniszewska and Denegri, 2013; Tritter, 2009). In theory, many countries around the world promote public participation in health, but in practice, the level of involvement of the general public ranges from direct involvement (where patients and the public actively participate in the making of decisions regarding health services and the use of resources) to indirect involvement (where health professionals and administrators elicit the views and experiences of the general public regarding health services to modify or develop health policies and programs tailored to their needs) (Tritter, 2009: pp. 276–277). Involvement can also be reactive (when it is shaped by a pre-existing agenda) or proactive (when the agenda is constructed by the general public) (Tritter, 2009: p. 277).

The type of involvement available is dependent on the local context, as it is influenced by previous attempts to ensure community participation, a history of success or failure, political engagement with an active public, the establishment of structural mechanisms for ensuring communication with the public, the designation of resources to promote public participation, and the ways in which strategies to guarantee participation are visualized by the population (Tritter, 2009). In order to provide a more in-depth discussion of community/patient/public involvement in health, we present two brief case studies from Cuba and Argentina.

Cuba

In 2006, Gallop Poll's affiliate organization in Costa Rica reported that 2/3 of all Cubans expressed a positive response to being asked if they had confidence in the Cuban healthcare system (Keeping Cuba healthy – BBC online 1 August 2006). While not perfect, the Cuban health system is doing many things right and is admired both within and outside of Cuba. What is right about the Cuban model are (1) the focus on prevention and (2) the role of public and patient participation (Whiteford and Branch, 2008). This model puts low-cost, universal interventions within the community and provides the personnel (family doctors and nurses, in particular) to carry out the interventions. 'Medicine-in-the-community' is a model developed in Cuba that puts a physician and nurse in every neighborhood. According to a recent BBC news report, Cuba has 1 physician for every 170 residents (BBC news). Neighborhood residents are obligated to be responsible for some portion of their healthcare while the State provides the rest. According to researchers, this reciprocal and symbiotic relationship between the patient and the state, and the active role of the Cuban patient and public in the primary healthcare system accounts for its success. Everyone is supposed to be visited at home at least once a year, often without warning, so the general practitioner can scrutinize a patient's lifestyle (Boseley, 2007). Some might consider this an intrusive prying into peoples' lives, however, as one Cuban physician noted when people became accustomed to his unannounced visits, they became more like visits among friends and communication was more open and honest. As a result, he felt he understood and communicated with his patients better as they came to understand him better (Whiteford and Branch, 2008).

While the State is responsible for the health of population, individual members of the population are also held accountable for their health. They are responsible for attending health fairs, doing exercise, and avoiding or reducing unhealthy practices such as smoking. Indeed, their participation is required and even mandated (Kath, 2006). In Cuba, healthcare policy development is very much a top-down process, but once in the neighborhood, the community plays a central role in the participatory playing out of those policies (Boseley, 2007).

What we can see from the Cuban primary healthcare system is the application of Kark's COPC model. It succeeds, in part, because of the effective involvement of the population and patients in accessing and improving their own healthcare. What we must also take into account with the Cuban primary health model is that it is also invasive and paternalistic, often challenging individual rights in its pursuit of controlling health outcomes. The relationship between the individual and the State in Cuba is complex, and it may be that in the healthcare arena it is most successful. That said, it must also be noted that the economic stress following the loss of the previous Soviet Union as a trading partner and supporter, has resulted in a loss of materials in most Cuban clinics. Cuba is rich in highly trained medical personnel and, reciprocally, in communities educated to access their services. In terms of public/community, patient involvement, the primary health system in Cuba is a successful model for other countries to follow.

Argentina

In the case of Argentina, the terms social participation (participación social) and the people's participations (participación popular) are used to describe a wide range of participatory strategies such as the monitoring of the distributions of medical resources, the approval of health programs, advocacy and the defense of health as a universal human right, consultation in the making of decisions, lobbying and the suggestion of changes in policies, and the involvement in health promotion activities (often at the level of disease prevention) (Zaldúa and Bottinelli, 2010).

In these strategies, NGOs, locally labeled as civil society organizations, are the main promoters of social participation in health. An example of this nongovernmental involvement is the creation of the Argentine Social Forum of Health and the Environment (Foro Social de Salud y Ambiente). This forum is

composed of "social, humanitarian, union-based, human rights, academic, territorial, and citizen organizations united to fight for the people's collective right to health" (Foro Social, 2002). In its aim to defend a universal health system, the Social Forum promotes social participation in health by prioritizing public involvement in the design, execution, management, and control of health policies (Foro Social, 2002). The Forum has made some notable advances such as arranging a meeting with representatives of local NGOs and the Vice Minister of Health in 2002 to discuss health-related issues and drafting a law on free health services and free transportation to health centers (Moyano and Escudero, 2007). Unfortunately, these initiatives have not yet been activated (Moyano and Escudero, 2007).

The Consulting Council (Consejo Consultivo) is a governmental group designated to promote social participation on a wide range of issues including healthcare. The purpose of this committee is to "generate a fluid exchange of information between government administrators and representatives of civil society" (CCSC, 2013). The council considers health to be a topic of collective interest and thus promotes open discussion with the public to establish the public health agenda and forward health policies (González García and Tobar, 2004: p. 18).

Social participation in health in Argentina has been promoted at both governmental and nongovernmental levels and has expanded from consultation of the local population about issues related to health services to their active engagement in the drafting of health policies and the raising of new issues. Much work still needs to be done to include sectors of society that are still being left out of conversations (such as young people or the elderly) to continue to foment the proactive direct involvement of the public and to establish long-term mechanisms of involvement that can bypass changes in political administrations (Anigstein, 2009; Belmartino and Bloch, 1984; Solitario et al., 2008). This last point has been the most notable obstacle in attempts to promote social participation in Argentina.

Conclusion

While the process of comparing health systems can be confusing and complex, it also can be an immensely useful activity. It allows the observer to become familiar with healthcare models other than his or her own, and equally importantly, it provides a template for assessing the various qualities of different models. As we review some of the lessons learned from the Cuba and Argentina examples we see that 'paper' participation as in Argentina is very different from the neighborhood popular participation in Cuba. Both Cuba and Argentina appear to have support for participatory healthcare from the very top of the political hierarchy, but only Cuba makes that support real and sustained in the community. But as CHS research clearly demonstrates, we must consider the differences is size, scale, economics, and political organization that Cuba and Argentina exemplify as we compare and contrast these realities. In sum, CHS is a critical element in our on-going analytical attempts to understand and improve healthcare systems globally.

Comparative History

Heinz-Gerhard Haupt, European University Institute, Florence, Italy

Abstract

Comparative history as a way of writing and conceptualizing history was propagated against national history during the 1920s, but developed mainly during the 1960s and 1970s. This development was encouraged by historical sociologists in the United States and the reception of social science approaches and results in historical research. Historiographies that are near to analytical methods and social sciences are more open to comparative methods. Their application started in economic and demographic studies before moving to political and social history. From the 1990s onward comparative history, which remained in all national historiographies in a minority position, was contested by the cultural transfer approach and transnational history. Both objected to comparison to be too much linked to the nation-state and to neglect the entanglement of the compared units.

Comparative History

Comparative history differs from other historical methods in that it takes an explicit line of questioning to compare two or more cases stemming from different contexts. The aim of this operation is either to bring out the similarities and differences of the different cases or to determine the scope of social scientific theories or theoretical approaches. Seldom does comparison itself lead to the formulation of theories. These characteristics distinguish historical comparison monographic work concentrating on case studies, from historical syntheses with an international scope and from implicit comparison, which indeed belongs among the analytical instruments of all historical work.

The Story of 'Comparative History'

Although the comparative perspective has appeared repeatedly in the history of historiography, it has only presented itself as a methodical instrument of explicit theoretical comparison since the 1930s. Of course, the historiography of the Enlightenment made use of comparison in its endeavor to grasp the specific characteristics of the historical process by means of universal historical types; in this context, Montesquieu, Adam Smith, and the cameralist J.H.G. Justi should be mentioned. In Scottish, English, French, and German Enlightenment literature as well, cultural areas and development stages were compared. Thus, just as the demarcation of the European model against non-European civilizations in the eighteenth century belonged to the arsenal of universal history, so did the belief that developed societies can trace their own history in that of less developed societies (e.g., Karl Marx). In this attempt, development thinking became closely intertwined with a Eurocentric perspective. This universal historical tradition persisted, carried on in the twentieth century by such diverse authors as Oswald Spengler and Arnold Toynbee, Karl Polanyi, and Shmuel Eisenstadt. Modern comparative history, however, is not rooted in this tradition. Profoundly affected by the experience of World War I and the traumas suffered by parts of academia under nationalistic exclusionism, comparative history established its argument for comparison as a fruitful enterprise particularly based on the results produced in neighboring sciences. Henri Pirenne, a Belgian historian and one of the pioneers of internationally comparative historiography, did admittedly make reference to comparative history in his opening speech at the fifth international conference of historians in Brussels in 1923, but with the intention of combating the narrowness of purely national perspectives and the subjection of historical research to functional ends. However, Marc Bloch and Otto Hinzte, two of the most influential forerunners in the field of comparative study, were even more active in taking up approaches from neighboring disciplines where comparison had long been a commonly practiced method. Historiography, as a historically comparative discipline, was a latecomer compared with other sciences. In fact, as early as the late eighteenth and early nineteenth centuries, various sciences had practiced comparative study successfully. Such works were produced not only in anatomy and physiology, but also in religious studies, jurisprudence, geography, and philosophy. Among them was that of F. Max Muller, the first *Introduction to the Science of Religion*, published in 1873. Thus it was no coincidence that Marc Bloch, in his 1928 essay advocating the practice of comparative history, does not cite historians, but rather Antoine Meillet and the broad range of scholars who had been carrying out internationally comparative linguistic research since as early as the nineteenth century.

In the development of modern comparative history, contact with the social sciences played the central defining role. Marc Bloch, whose works on the 'royal touch,' on the agrarian history of England and France, and on the different forms of feudal society in Europe up to 1940 provided important examples of comparative study, had received theoretical stimuli, above all from Emile Durkheim. Durkheim saw comparison as the sociological method *par excellence*, enabling the delineation of the fundamental characteristics of social types. Bloch used this method, for example, in his analysis of feudal society when he concentrated on its dominant dependency relationships. Otto Hintze, who was among the pioneers of historical comparison, also took the work done in the social sciences as his model. He adopted the concept of the ideal type from Max Weber and went on to construct an ideal type concept of feudalism. He then applied this to the various manifestations of feudal domination that he found to be particularly pronounced in

Russia, Japan, and the Islamic countries. In the period following World War II in particular, the number of theoretically based works with an internationally comparative perspective increased. It was largely inspired by historical sociology. On the one hand, it profited from the broad scope of sociology's macro comparisons that were limited neither to a specific epoch nor to a specific continent. These comparisons studied different national cases, using stringent argumentation to examine theoretical questions. Thus Barrington Moore inquired as to the role of agrarian development in the emergence of either democracy or dictatorial fascistic regimes in a broad comparison of six national cases, while Jack Goldstone compared revolutionary crises of the early modern age in Europe and Asia. On the other hand, however, it was only the historical research in monographic form that made available to historical sociologists the theses and research results that would enable them to carry out extensive comparisons. The stimuli obtained from historical sociology were also accompanied by critique of its generalizations and its handling of the historical state of research, which it did not always improve upon extensively. Nevertheless, historical sociology provided an important stimulus to comparative history. Its works elicited an increasingly favorable response in the 1960s to the extent that history was open to theoretical questions, and gradually after 1970, these works were also emulated. The theory of modernization, which originated mainly in the United States in the 1950s, provided a powerful comparative impetus as well, and elaborated parameters of development against which it measured individual societies. The successful combination of market economy and political democracy was its criterion for modernity. In this sense, the vague but positively cast concept of 'modernity' was used widely in historiography on the nineteenth and twentieth centuries; it emphasized structures, functions, and interdependencies among the different parts of systems more strongly than their historical individuality. In individual historiographies – particularly in those countries catching up in industrial and political development – the comparison to the Anglo-Saxon 'leader' countries soon became one of the standard lines of argumentation. In the West German debate about the long- and medium-term causes of National Socialism, structural deficits were identified in comparison to Anglo-Saxon development, which itself was admittedly highly typological and idealized: these included the feudalization of the German middle classes, a general deficit in the middle-class way of life, the exceptional proximity of middle-class life to the state, and the persistence of privilege-based social orders in the old and new middle class. Especially in this debate about Germany's *Sonderweg* ('unique path') – but in Italian historiography as well – it was no longer just the linear and unceasing advance toward modernity that was at issue, but the ruptures, contradictions, and deficits in the development.

Disciplinary and National Patterns of Comparative History

Within historical writings, comparative methods by no means penetrated all disciplines to the same degree or simultaneously. They emerged earlier in economic history, population history, and political history than in social history, gender history, or cultural history. As early as 1957, the Economic History Association dedicated one day of its annual conference to comparative economic history, and it was no coincidence that a year later, economic historian Sylvia Trupp founded the journal *Comparative Studies in Society and History* with the expressed goal of publishing studies of an interdisciplinary and comparative nature. In Europe, the English model of industrialization and its spread was the central topic of the comparative studies that appeared even before 1960. The most broad-based and influential comparative analysis was produced by Alexander Gerschenkron, who studied the basic similarities and differences within the European process of industrialization, inquiring into not just the different answers to similar challenges, but also the functional equivalents among European societies. He explains the differences in development on the basis of both the specific position of the individual economy in the system as a whole ('relative backwardness') and the influences generated by developed societies. Walt Rostow's 'stage theory' of economic growth also provided an impetus to comparative economic history after 1960, as did Simon Kuznets's quantitative studies. Rostow's thesis that every society has to go through similar phases of economic growth and that therefore each society's position can be identified against this background was almost a direct invitation for checking by historical comparison. Kuznets, in contrast, instead emphasized the uniformity of modern economic growth, although without ignoring its national diversity. His three-sector thesis also led to comparative studies.

In historical demography, in 1963 at Princeton, Ansley Coale began comparing 600 European regions to answer the question of whether and why the birth rate was declining in Europe; this was called the European Fertility Project. Although the project did produce convincing demographic results, the explanation of demographic behavior on the basis of historical macro processes came under criticism. The reasons for the early comparative studies of political movements and institutions can be found not only in the field of 'comparative politics,' which gained importance in the USA in the 1960s, but also in a specific approach to research within political science. This approach applies to institutions that can be classified under the general type of democratic systems, but that nevertheless take on specific forms. Research on resistance movements and on social systems or constitutions paved the way for the advancement of comparison in social history.

Nevertheless, since the mid-1960s, sociohistorical comparison has taken on a leading role, showing a remarkable breadth of research and differentiation in approaches. In Europe, at least a handful of papers have been published every year since 1970 on comparative social history, none limited to a specialized area, but including the history of the family and social classes, and the development of the social state, the city, and education. These studies have been focused mainly on three central issues. First, they deal with the explanation of national peculiarities that often – because of political events – are seen as characteristic of the social development of the last few centuries. In the debate about the German *Sonderweg*, this orientation of comparative sociohistorical research has taken its most comprehensive and probably also most fruitful form as a scientific heuristic device. Second, they focus on the

different pathways of individual European societies into the modern age: their distinctive features are identified above all in comparisons between different societies, and between European and non-European cultures. A third focal point has been the European model and its social characteristics. All these studies have demonstrated methodical diversity in both quantity and in quality; have integrated social, political, and economic factors; and have focused attention on both linear and cyclical developments. Furthermore, they have compared societies as well as parts of societies.

European historiographies have not all made use of the comparative method to the same degree. Surprisingly, Marc Bloch's appeal in France went unheard for many years, as French historiography was and continues to be strongly oriented toward monographic work and highly skeptical of theory. In Great Britain as well, historical comparison did not catch on because of the dominance of national history and the distance from the social sciences. In Italy, comparative history remained on the periphery – despite the proximity of many historians to debates in the social sciences – because of the strong regional orientation. In West Germany, Scandinavia, Switzerland, and Austria comparative work was rather limited within total historical production, even though the number of comparative works was significantly higher than inside other European historiographies. Although sociohistorical comparison was particularly strong in Germany, this was mainly a result of both debate on the approach toward the German *Sonderweg*, which was dealt with in many comparative historical essays, and the explicit discussions of social theories and proposed explanations that characterized modern German social history. In general, one may assume that internationally comparative history had a difficult time gaining a foothold wherever the relation to theory was weak, and wherever attempts to explain national patterns of development in the philosophy of science remained only peripheral. Before 1989, this was the case in Iberian societies as well as in Eastern Europe. Historians in the United States, where, according to Raymond Grew, comparison is a weak point rather than a strong one, has not only brought forth a series of excellent comparative studies on European history, but also practices transepochal and transatlantic comparison more intensively than does European historiography. Among the comparative works on Europe, those of Charles Tilly, Peter Baldwin, and Susan Pederson are particularly worthy of mention. The study by Arno Mayer on the Holocaust, which he sees in the tradition of the Crusades and the Thirty-Years' War, takes a transepochal and internationally comparative approach and presents a comparative tableau of the situation of Jewish people in Eastern European societies in the 1930s. Transatlantic perspectives are opened up by those studies that place slavery in the South, the frontier problem, and the situation of migrants in a larger, multinational context. In gender history, the comparison of male and female roles was for a long time the constitutive element of analysis, and only recently have theoretical, internationally comparative studies been produced. These have concentrated on institutions or subareas, which, like social laws, have attained a special meaning for gender roles. Modern cultural history as well, which discusses the creation and relevance of stems of meaning, rituals, and symbols, has concentrated thus far on national configurations and ascribed little importance to international comparison. In historiography on classical antiquity, the Middle Ages, and the early modern age, comparative studies were carried out, comparing rulers, regimes, and individual institutions. Because of the international character of political systems, the national aspect decreased in importance as a unit of comparison. However, theoretically oriented comparisons remained scarcer in this area than in the historiography on modernity.

Functions of Historical Comparison

The comparative method pursues two goals alternately. On the one hand, it seeks to accentuate the distinctive feature of each individual case, and on the other, attempts to derive evidence on general developments from case studies. While historians tend toward the first approach, the second is more prevalent among social scientists. Comparative historical studies do, however, also deal with the question of commonalities. Four functions are granted to comparison in these studies: a heuristic function, a contrastive function, an analytical function, and a distancing function. Comparison plays a heuristic role when it alone can offer explanations and reveal phenomena that had been unknown or inadequately known up to that point. This function was already referred to by Marc Bloch, who, based on his knowledge of the English enclosure movement, sought an equivalent in French agrarian history. Founding his thesis on research in regional history, he dates the disappearance of collective rights in Provence as early as the fifteenth century, and concludes from this that similar movements took place in France not only earlier, but also under other conditions. Thanks to the comparative method, Bloch was able to discover a characteristic of French agrarian development through his studies of the agrarian history of other countries.

Historical comparison can be called contrastive when it serves to define more precisely the special features of a specific case. Above all in German–French comparison, this method was used to bring into bold relief the particularly xenophobic character of German nationalism in the early nineteenth century, the insurance character of Germany's social security system, and its unique characteristic of having a highly educated middle class. Comparison of Italian and Anglo-Saxon developments brought out the backward state of Italian industrial development, its lack of a modern party system, and its unique feature of having a patrician, noble class. Depending on the country selected for comparison and the logic behind this comparison, specific characteristics of the mostly isolated national case but also of regional patterns of development are illuminated and brought into clear contrast against the totality. At least two problems emerge in this perspective: the further the development stage in the reference country or region deviates from the individual case in question, the less suitable it is for defining the specifics of the case beyond mere identification of general deficits. If one measures the economic development in Italy in the nineteenth century using as a yardstick the conditions that promoted industrialization in England, one can only determine that these conditions were lacking in Italy, but cannot identify the specific conditions for the economic growth that took place there. The more comparison is used to highlight the contours of a specific case, the more typological and

reductive the resulting picture might be. International case studies written in comparison to the German case with the aim of presenting a general view of the livelihood and benefits of German white-collar employees have only rarely provided convincing analyses of the individual national developments in the employee milieu. This inherent bias of comparison should be borne in mind in each case. Comparison has an analytical character when it either tests a scientific hypothesis or identifies constellations of causes in a specific situation. The thesis that a causal relationship exists between capitalism and feudalism is relativized by the fact that strong fascist movements did not emerge in all capitalist societies; they were able to develop only under specific conditions. Jurgen Kocka qualified this assumption in his comparison of American and German society between the two World Wars. In a study of the French, Russian, and Chinese revolutions, Theda Skocpol inquired as to the results of collapsed administrative apparatuses, broad peasant rebellions, and movements among political elites, thereby demonstrating the extreme diversity in the constellations of causes that explain the outbreak of modern revolutions. In this analytical approach, comparison can also serve as an indirect experiment. When phenomenon *a* is ascribed to cause *b*, the historian can test their hypothetical connection by looking for constellations in other societies in which *a* appears without *b*, or where *b* exists without leading to *a*. This heuristically useful procedure is distinguished from experiments in the natural sciences in that here, the *ceteris paribus* conditions are seldom given.

Comparison has a distancing effect when it offers another perspective to observation and analysis. It can produce surprising discoveries as well as relativizing the tradition-based context of national historiographies. Especially for those historiographies that are deeply embedded in a national context, comparison can open up new and often broader vistas. When confronting comparisons with other reference cases – especially those from other cultures – not only does one gain experience with different types of question and method, but also fundamental assumptions of one's own historiography can be revealed and their problems expounded. The comparative view can also contribute new insights: Skocpol, for example, uses the comparative method to shed new light on the similarities between the French Revolution of the eighteenth century and the Chinese revolution of the twentieth century in her comparison of revolutions, and between the cities of France and Japan in the eighteenth century. Taking into consideration the variety of alternative pathways into the modern age prevents exclusive concentration on the European development path and offers insight into those conditions of European development that cannot be generalized.

Methodology of Comparison

Although comparative history does not possess its own methodology, it does present particular methodological problems in bold relief. Historians have used the proximity of their work to original sources as a special proof of its scientific nature. The goal of reconstructing history via a multitude of sources in as comprehensive a manner as possible is one of the fraternity of historians' standards. This fundamental methodological principle to a certain degree evades historical comparison. In so far as it compares more than two cases, it depends more heavily on secondary literature than on the evaluation of a consistent body of sources. Thus, it also faces the problem of having to assess adequately the historiographic context, where each individual work of secondary literature interprets the original sources in its own specific way. Another of the principles of historical study is that individual aspects of reality cannot be understood separately from their place within a totality or within a historical development. The full meaning of details comes into focus only when looked at in synchronic and diachronic perspective. The method of isolating variables – a common practice in empirical social research and political economy – can and should be used within the framework of research projects, but is inadequate for representing the results of research. Comparisons can trace diachronic development processes in their similarities or differences, but they can also examine transepochal cases along one specific line of questioning. For example, Raymond W. Goldsmith studies the premodern financial systems in ancient Mesopotamia, the Indian Mogul Empire, and England under the rule of Elizabeth I. For him, what is of interest is not how an epoch can be characterized, but the contribution of different states and ages to a central line of questioning. Comparison can also evade both chronology and the total context in question: one separates out the individual cases, subjects them to examination from a specific perspective, reduces their complexity, and studies them as exemplary cases belonging to a 'universal,' the *tertium comparationis*.

Because of this isolation and reduction, the methodology of comparison enters into a relationship of unresolvable tension with fundamental principles of historical study. What has proven to be a rule of thumb is that the loss of context in comparative study is less severe the smaller the number of reference cases. By choosing medium-range theories and argumentation on a moderate level of abstraction, one limits as far as possible both the loss of concreteness and the distance from the object of study. To do justice to the diverse kinds of relationship affecting a particular case, comparative historical studies include processes rather than constellations, and link the analysis of individual situations with questions derived from the historical study of relationships. The integration of individual cases into the social context can be intensified through close attention to the linguistic and conceptual specifics that define and influence these contexts. Despite all of these methodical problems, historical comparison also has a positive impact on historical research by raising its consciousness about the extent and limits of different approaches, the implicit premises of scientific study, and the coherence of the total context. It opens up historical study to theoretical reflection.

The unit of comparison changes according to the line of questioning and the information being sought. For a long time, a national framework of study was dominant in the science of history, both because this framework influenced the problems being studied and also because answers to questions of national history were sought in comparison. Research on nationalism and welfare states, democracy, and religious denominations has been given a privileged place in the national framework. This national approach has been called

into question by two developments: microhistory and intercultural history.

Microhistory has brought increased interest to local, often unique sources and problems that give a privileged role to the viewpoints of the people involved, and which – because of the emphasis on individuality – had been excluded previously from methodical comparison. In addition, this shows the importance of another area that calls into question the self-assuredness of past research on national historical developments. For the study of family constellations and famine unrest, local frameworks present themselves as the most appropriate, while for the analysis of linguistic dialects or industrialization, the regional level is preferable. As the study of history becomes increasingly global, the national level will decrease continuously in significance. This does not just apply to colonialism, the migration movements of the nineteenth and twentieth centuries, or the global economy that has been developing since 1880. Marc Bloch pointed out as early as 1928 that the development of manorial rule in the Middle Ages and early modern age in individual localities and regions cannot be understood independently of the decline of money rent throughout Europe.

In so far, then, as one seeks to identify the special features of Europe's development, it is necessary to include non-European cultures, which, however, should no longer serve merely as a foil as they did for Max Weber, but rather be examined with a differentiated view to their independence and specificity. In order to obtain a new perspective, Jurgen Osterhammel proposes a new approach: instead of analyzing non-European cultures from a European standpoint, one should take the opposite viewpoint and determine European specifics from the standpoint of non-European cultures. The methodical problems of such a perspective are as obvious as its advantages: these include on the one hand problems of languages, the knowledge of often very different historiographies, and aggregation of data that decrease in meaningfulness and are often statistically antiquated, and on the other, a new view of known developments, and the opening of a wider sphere of activity and relationships.

In particular, the history of transfer processes brought attention to the problem Galton is formulating for ethnology. He questioned whether two or more cases can really exist independently alongside one another, or if they are enmeshed in a visible or invisible web of relationships that influence them decisively. The question of how specific constellations develop through direct influence, appropriation or imitation of foreign models does indeed increase the complexity of comparison, but in no way replaces it. As is well known, Marc Bloch extolled the study of societies in the same epoch that are neighboring, mutually influential, and subjected to the same macro changes as one of the ideal methods of historical comparison.

Comparative History's Agenda and Unsolved Problems

Comparison poses methodical and theoretical problems for the science of history, but at the same time challenges it, and can even work as a factor to increase method-consciousness and support theoretical reflection. Currently, an expansion of previous approaches and fields of comparison in the following directions could be considered: Until now, comparative studies have limited themselves to defining the range and meaningfulness of theories. Such problems as whether Weber's class theory is appropriate for the history of the European middle class, whether Pierre Bourdieu's concept of cultural capital is useful for an analysis of intellectuals, or whether Marx's theory can be applied to modern revolutions – and whether all of these can explain more than just national cases – have been the focus of interest thus far. However, the question of what changes must be made in theoretical concepts if they are to explain more than one national development and encompass a multitude of empirical cases has seldom been asked. Therefore, comparative history has contributed little to the development of theory thus far, and has seldom taken the step to formulate theoretical alternatives by relativizing existing approaches.

During the last 20 years, transnational and global history approaches are challenging the practice of international comparative history that focussed on national case studies. The concept of transfer history promoted by the French cultural historians Michel Espagne and Michael Werner draws attention to the relationship between two cultures and highlights the importance of cultural mediators as well as the transformation of the transferred cultural product. It questions the image of culturally homogenous societies and stresses the importance of foreign contributions. Transnational history, started at the beginning of the 1990 in the United States is not a method, but a perspective of analyzing historical processes. It stresses the linkage between nations, regions, and towns in a global, European, or transnational perspective and is near to diplomatic and international history writing. Its main goal is to promote a history beyond the nation-states and to underline the dynamic character of movement and interpenetration between the analyzed units. The most important results have been obtained in analyzing migrations and migrants. But also studies on transnational networks as worker's international or international organizations as the World Bank or Amnesty International have been undertaken. Even if this approach tends to privilege an optimistic vision of transnational realities and should be more attentive to the effects of transnational relationships, it motivates comparative history to integrate the 'entanglement' between the compared units in their studies. As much as comparative history needs the knowledge of entanglements, as much research on entanglement must use comparisons.

Contemporary processes of globalization have left their mark above all on the capital and labor markets, but have also called into question the national contexts of thinking prevalent in the sciences. On the one hand, historical research in an international and global framework is becoming more important. Comparisons between civilizations and continents, Empires and regions are an important part of it. On the other hand, the individual societies themselves have become complex 'melting pots,' as reception and diffusion of cultural models, social modernization, and social and cultural coding have merged in them, accompanied by national-historical and global-social influences. With the increasing demand for an adequate survey of contemporary society, the demands placed on a theoretically based, methodically differentiated comparative history will

increase as well, expanding the spectrum of questions with which history will be interpreted.

Comparative Method in Anthropology

Andre Gingrich, Austrian Academy of Sciences, Vienna, Austria

Abstract

This article presents comparison in anthropology as the field's third main methodological inventory, together with ethnographic fieldwork and historical anthropology. A new pluralism of comparative procedures is discussed by examining binary, regional, temporal, distant, and fluid versions of comparison. Finally dissociated today from previously predefined connections to grand theories, anthropological comparison primarily is of a qualitative orientation, remaining closely connected to fieldwork insights while moving from it to an additional level of careful abstraction that may allow for better distinctions between particularities and commonalities in human sociocultural lives.

In its most elementary dimensions of meaning, comparison designates a basic activity of the human mind by the way of implicitly or explicitly identifying similarities and differences among two or more sets of experiences, impressions, and related phenomena. Any comparative perception thus would usually contain a simultaneous interplay of both, similarities as well as differences. The general concept of comparison therefore includes a continuous range of various versions of that interplay. One end of the continuum is represented by the dominance of identifying sameness as well as parallels and similarities. The other end of the same continuum can be seen in those instances when the perception of contrasts and difference is the most important. In fact, the identification of differences may be prevailing in the process to such an extent that some scholars prefer to classify 'contrasting' as a separate mental process. The present entry, however, shares the alternative thesis that contrasting is better understood as one version of comparison with a specific imbalance in the regular interrelation between finding similarities as well as differences. In such a perspective, comparison is closely related to, and intersecting with, other main mental activities and capacities such as recognition, memory, anticipation, intuition, or decision (Bloch, 1998).

Beyond their general relevance in human life, mental activities also are intrinsic to the specialized realm of research processes. In this sense, comparison also designates such elementary procedures of academic inquiry that raise systematic questions about similarities and differences among the phenomena under examination, and about their causes. This is why comparative questions about similarities and differences may be inspired by, or give at least rise to, considerations about the particular (or the unique), the specific (or a limited class of phenomena pertaining to the same set or class), and the more general. It follows that comparison is part of a variety of methodological procedures in academic research that basically are inspired and directed from the outset by the central research question(s), and in turn by the theories and empirical insights informing that central research question (Palmberger and Gingrich, 2014). Quite rarely is the central research question primarily or exclusively defined by theoretical deliberations alone ('deduction'), or by empirical insights alone ('induction'). Rather, in anthropology and related fields of the social sciences and humanities the most common instances of identifying a central research question directing comparative and other methodological procedures emerge out of the interplay between certain theoretical deliberations and empirical insights ('abduction') (Reichertz, 2004).

As an element in comparison at large, anthropological comparison shares the main features of the general type of mental operation discussed so far. In addition, it is characterized by a number of constellations that are more or less specific to this academic discipline and a few of its neighboring fields. For sociocultural anthropology during the early twenty-first century, comparison in this sense represents the third central element in the field's key methodological inventory (Gingrich, 2013). Ethnographic fieldwork in its many changing varieties comes first, ever since fieldwork was established as the field's primary mode of empirical research. Historical methods in anthropology gradually have come to be globally acknowledged during the final quarter of the last century as second to that. Comparative methods went through much more contested times in anthropology, before they became widely recognized again as the third key methodological element in the anthropology of the globalized present.

Comparative Approaches in Anthropology's History

Prior to the emergence of the current phase in anthropology, with its strong emphasis on transnational and global contexts, the field went through a series of crises and critical self-examinations during the last quarter of the twentieth century. Those crises and intellectual movements contributed to the dissolution of main national (and quasinational) traditions which had dominated much of anthropology's history throughout the twentieth century. Each of these main national traditions, and of the main phases of evolutionism that had preceded them, pursued such comparative procedures that served their respective theoretical purposes. In that sense, each and every 'meta-narrative' in anthropology's history before the 1980s had its own comparative priorities.

Evolutionism compared local societies and cultures by criteria such as differing socioeconomic, or organizational and ideological complexities, taking them as examples for past stages of human development (Sanderson, 1997). Diffusionism compared cultural features by criteria of differing aesthetic appearance and morphological form, taking them as evidence

of respective distance to previous external influence emanating from possible centers of origin (Schweitzer, 2011). Historical particularism, by contrast, remained thoroughly skeptical about most forms of comparison whatsoever. This was in line with the general assumption that particular cultures were so unique that they could hardly be compared against each other at all, except perhaps within one area of distribution (Darnell, 2008). Functionalism, on the other hand, compared local societies by criteria of institutional differentiation, which were assessed as primary indicators of social integration (Kuklick, 2008). Structuralism, finally, compared elementary relations in myths and in marriage alliances to elaborate its theories of the ways by which the human mind operates (Parkin, 2005) – and so on and so forth. In short, during the era of anthropology's grand theories and national traditions, comparison largely was reduced to a qualitative tool at the service of proving a grand theory's main assumptions and premises.

This instrumentalization of comparison by 'national' qualitative priorities then became radicalized, homogenized, and in a certain way, universalized by the elaboration of an *Atlas of World Cultures*. In this context, G.P. Murdock and his associates established the 'Human Relations Area Files' (HRAF). On the basis of the HRAF, comparison was developed into a generalized quantitative research tool to document and explore the global distribution of correlations between identified sociocultural criteria across cultures ('hologeistic sampled comparison' or cross-cultural method) (Sarana, 1996). In many ways, that quasiclimax in anthropology's comparative record of the twentieth century eventually turned out to be an anticlimax. For methodological reasons as much as for its contexts of emergence (during World War II Murdock's original project had been inspired and commissioned by US government interests (Price, 2008), to whom it maintained a certain affinity after 1945), comparative work with the HRAF fell out of fashion in anthropology since the 1960s and 1970s. Together with increasingly intense and more differentiated internal criticism of anthropology's grand theories and their underlying metanarratives, comparison as understood in the previous mainstream manner went into a period of demise that lasted until about the end of the twentieth century.

A New Pluralism of Procedures in Anthropological Comparison

Together with the emergence of transnational and global orientations in anthropology around the last turn of the century, comparison has returned back into the field's main methodological tool-kit, yet in more modest and in more pluralist forms than ever before (Holy, 1987; Gingrich, 2012). Key factors related to anthropological comparison's reemergence were the growing interest in the field's contemporary agenda, as well as questions related to anthropology's legitimacy as an academic discipline, and finally, developments in neighboring fields: In philosophy, sociology or history, the postmodern moment went by somewhat faster, and developments there indicated the sustained relevance of comparative factors (e.g., 'constant comparison' in sociology's grounded theory or wider comparative perspectives in postcolonial historical research). Inside anthropology, the rejection of old metanarratives at first had made versions of relativism and particularism somewhat more attractive for a while. Yet it soon became obvious that an academic field could not sufficiently address any larger issues, nor sustain any credibility and legitimacy if based on nothing else but particularities. At the same time, the growing impact of various dimensions of globalization also redirected researchers' attention increasingly toward inquiries about what humans share and where they differ in their interactions with that impact.

Anthropological comparison thereby gained new relevance in today's contexts. It now is largely dissociated from predefined connections to any metanarrative or general theoretical claims, and in that sense holds a status that is similar to current principles of participant observation and ethnographic fieldwork. Anthropological comparison primarily follows qualitative procedures, with quantitative elements at best playing a secondary role. The choice of examples to be compared usually follows the principle of 'controlled comparison' (Eggan, 1954): random choice is avoided, and the cases to be compared are thoroughly theorized and checked at first. This has led to today's new pluralism of comparative anthropological methods (Gingrich and Fox, 2002), among whom the most widely applied are these five:

1. *Binary comparison* relates phenomena in two different sociocultural settings with each other. Together with Laura Nader (1994), it can be argued that at least in an implicit way, almost every anthropologist pursues this form by comparing aspects of his or her fieldwork's host context with the researcher's home contexts (unless the two are identical). For reasons of transparency and communication, it is worthwhile to make these elementary forms of self-reflexivity explicit. This also helps to minimize the dangers of any stereotyping in terms of 'us vs them' that are in fact inherent to this approach. Carried out in a balanced way, however, binary comparison may provide profound cultural critique (Marcus and Fischer, 1986) and rich contrasts (Dumont, 1994; Lock, 1995; Sahlins, 2004).
2. *Regional comparison* is the best established version in the anthropological record (Fortes and Evans-Pritchard, 1940). While the temporal contexts of compared examples should be kept within fairly similar spans of ranges, three or more cases from the same – smaller or larger – regional sphere are compared against each other. This procedure requires careful reflection and theorizing about the region and the criteria to be compared in question. Without this, inherent potentials about envisioning some kind of 'cultural area,' 'cultural circle,' or 'style province' are difficult to avoid (Fillitz, 2002). Yet at its best, regional comparison may provide insights into the specificities of certain trajectories among multiple modernities or into specific yet not universal ways of the past (Godelier and Strathern, 1991; Kuper, 1982)
3. *Temporal comparison* relates examples from different instances along a time line with each other, while keeping the regional contexts fairly constant. If the earlier or earliest instance in temporal comparison is not thoroughly theorized, then misguided assumptions about 'origins' and 'archaic conditions' might misinform this procedure. In its appropriate and accurate versions, however, temporal comparison will elucidate further historical research, as

well as to synthesize some of its previous results (Comaroff and Comaroff, 1991/97; Tambiah, 1977). By definition, temporal comparison in anthropology has to rely more substantially than the other four versions on results from neighboring fields such as archaeology or history, yet it operates with anthropological concepts and methods that often also include insights derived from fieldwork.

4. *Distant comparison*, also called 'self-reflexive, controlled macro-comparison'. When three or more cases are compared with each other across widely different spatial and/or temporal contexts, then such a 'distant' comparison usually follows a well specified query: examining the conditions for the emergence of substantial urban cultural growth in Calcutta of the mid-nineteenth century, Vienna of the nineteenth/twentieth centuries' turn, and San Francisco of the mid-twentieth century was an example for such a query by Ulf Hannerz (1992). Tony Robben's (2010) exercise in applying a number of known insights from warfare elsewhere to the unknown situation in then Iraq represents another case in point. Both examples show that distant comparison in most cases has to rely on rich historical and anthropological work being already completed, so that the main comparison then can take place *a posteriori*. Perhaps the most obvious risk in this procedure – as in fact with all *a posteriori* comparison – is the likelihood that the kind of empirical evidence is not sufficiently available which would allow to substantiate the theoretical and comparative ambition. Once that is the case, however, distant comparison allows for fairly generalized results, and for theorizing with unexpected outcome (Gingrich, 2002).
5. *Fluid comparison* – also called 'shifting time–space comparison' – follows the flows of a phenomenon through time and space. This may be the production and usage of sugar cane in different eras and continents (Mintz, 1985), the rise and spread of Islam, or the expansion of capitalism around the globe (Wolf, 1982). By contrast to distant comparison, fluid comparison avoids jumping too much across temporal or spatial distances, but instead it traces lines of continuity and change. In its empirical dimension, this perhaps is the most demanding procedure, simultaneously also requiring substantial theoretical rigor with a potential of highly rewarding results if successfully carried out.

A number of examples have been indicated in this provisional overview of five main versions of current anthropological comparison. The examples illustrate that many among this field's main and pioneering works around and after the last turn of the century in one or the other way strongly relied on comparative procedures. These works range from classic works and milestones in economic and medical anthropology to transnational approaches, from cutting-edge work in historical anthropology to advances in anthropology's study of violence and conflict to the field's contributions in migration studies, cognitive research, and to the anthropology of art. Obviously, comparative approaches in anthropology have entered a new phase of respect and attraction. At the same time and because of this, it seems appropriate to emphasize that anthropological comparison is no self-serving endeavor. It is useful and in place to add an a priori or an *a posteriori* comparison to a research perspective whenever that promises additional insights that may not be delivered in sufficient ways by other forms of investigation. Identifying the *purpose of comparison* therefore is crucial – whether it is inspired by outlining the wider relevance or the specificity of the main examples under discussion, whether cultural critique is the driving motive or grasping certain aspects of wider developments such as the results of transnational flows or the potentials in multiple modernity. In the end, at their best the various versions of comparison therefore do serve conceptualization and theorizing at least by way of exclusion, yet sometimes also through substantiating an argument.

Current Debates

This final section discusses three main points of contemporary debates on comparison in anthropology:

1. The loose and possibly incomplete differentiation into the five versions of binary, regional, temporal, distant, and of fluid comparison already is providing elements of new answers to old questions about the choices and the limits of comparison. The kinds of choices that come along with each of these five main versions simultaneously depend on the guiding research question, as well as on the available empirical evidence and its interpretation. It is also obvious that the limits of comparison cannot be predetermined, neither for the individual cases nor for the wider comparative range into which they are integrated. It seems safe though to emphasize that these limits may remain fairly fluid and fuzzy in most cases, with possible exceptions in medical and ecological contexts (Bernard and Ryan, 2010: pp. 145–160). This also opens up these comparative methodological strategies to a plurality of epistemological orientations inside anthropology, which may range from a Wittgenstein-inspired focus on 'family resemblances' to more conventional versions of pragmatism, of speculative realism and to some among the more recent elements of rationalism.
2. If theory-inspired research questions and empirical research contexts do or do not attribute sense and meaning to comparative projects, then old-fashioned notions about a *tertium comparationis* become obsolete. Derived from the rhetorical and literary traditions of late antiquity, that principle necessarily required assumptions about an 'essence' that had to be envisioned inside all objects of comparison to make rhetorical or literary comparison meaningful. Now, most anthropologists would not feel comfortable with, and would not want to subscribe to a methodological point of view that speculates about any shared 'essence,' reducing comparison to a search for commonalities only while disregarding diversity, and being deeply rooted within the narrow constraints of Aristotelian logic at that. By contrast, qualitative anthropological comparison in all its main versions strives to remain open about the outcome of the comparative endeavor. While the Aristotelian assumption of a *tertium comparationis* reduces comparison to a function of objectivist essentials, anthropological comparison elaborates *criteria of comparison* in close dialogue with the ethnographic record. The point is that the researcher has to develop such criteria of comparison that are derived out of the main research question, while simultaneously having a capacity to actually address

the empirical features in question in each case example to be compared. In this manner, the criteria of comparison cross-cut all the cases used and investigated during a comparative project, eliciting similar or different results from each of them (Gingrich, 2012).

3. A final point returns to the relation between anthropological comparison and ethnographic fieldwork. Like all of sociocultural anthropology, its comparative methodologies rely on the results of ethnographic fieldwork and remain fairly close to them. Even those forms of comparison that rely on one or the other variety of historical anthropology usually do include some intersection with ethnographic fieldwork results. In that sense, anthropological comparison at large is not an independent methodological procedure. It gives priority to ethnographic fieldwork, and to a substantial extent it depends on its outcome. One could of course add that the reverse is also true: no ethnographic fieldwork could ever take place without some comparative exercises being carried out prior to fieldwork (including decisions about the choice of topics and of field sites), and during the course of fieldwork. After all, it is only through comparing again and again the different encounters and interactions during fieldwork that the ethnographer will distinguish situations in which certain elements follow some standard or repetitive order from others in which the particular or the accidental is prevailing. In that sense, the relation between ethnographic fieldwork and one or the other form of comparison is reciprocal. Yet within the tension between empirical findings and their interpretation at one end of the spectrum, and theorizing at the other end, fieldwork by definition is closer to the empirical side, and comparison is closer to theorizing. Due to a usually small number of examples to be compared, the amount of abstraction remains fairly modest in anthropological comparison. Writing or filming an ethnographic account already per se represents a first level of unavoidable abstraction and interpretation. Anthropological comparison is the next and second level in the same process – to the point that one may sometimes even speak of a 'thick comparison' that remains faithful to its contexts of emergence (Gingrich and Thelen, 2012; Niewöhner and Scheffer, 2010).

Abstract

The 'comparative method' refers to a set of statistical methods and ideas for studying adaptive evolution across groups of biological species. Comparative methods are an important branch of evolutionary studies primarily because of their ability to reveal broad or general evolutionary trends, and to provide insight into adaptive evolution. In recent decades, it has also been appreciated that they can be used to study evolutionary trends in human societies and so have begun to be widely used by anthropologists as well as biologists.

Overview

The 'comparative method' refers to a set of statistical methods and ideas for studying adaptive evolution across groups of biological species (Figure 1(a)). We can illustrate their use by examining one of the classic comparative relationships – that between the size of an organism's body and the size of its brain (Figure 1(b)): brain size increases steadily and predictably with body size in mammals, and this broad relationship also holds within most other animal groups. What makes the relationship

Figure 1 Mammalian brain and body size. (a) A phylogenetic tree of 538 mammals (the phylogeny is adapted from Bininda-Emonds, O.R.P., M. Cardillo, K.E., Jones, R.D.E., MacPhee, R.M.D., Beck, R., Grenyer, S.A., Price, R.A., Vos, J.L., Gittleman, and A. Purvis. 2007. The delayed rise of present-day mammals. Nature 446(7135): 507–512; (b) Plot of brain mass versus body mass for these 538 mammals. They are color coded according to order. Note the logarithmic scales; (c) The model predictions for a GLS model that always the slopes and y-axis intercepts vary by mammalian order. See text for further discussion.

striking is that across a range of animals from the size of mice to elephants, if we know the animal's size we can predict the size of its brain with surprising accuracy.

The natural interpretation of such comparative relationships is that they reveal general adaptive trends. This is to say that the organisms that individually evolved to conform to the predicted trend were somehow more fit or suited for survival than those that did not. Thus, as animals evolve to become larger, a larger brain is required for 'housekeeping' functions as well as simply to monitor the increased number of neuronal signals coming from the organism's body and internal organs.

Larger animals also tend to roam over wider areas, and a larger brain may be needed to, for example, keep track of spatial relationships or to remember where things are found. Small animals could have larger brains, but if the adaptive argument is correct, a relatively large brain in a small animal might be a disadvantage. Brains are costly to produce and maintain (they must be supplied with blood and nutrients) and so animals are unlikely to evolve 'spare capacity.'

One of the strongest pieces of evidence that a comparative relationship represents an adaptive trend is to show that it has arisen independently on more than one occasion. For instance, if we examine the relationship between brain size and body size separately among the different 'orders' of mammals, we get more or less the same result in each group (Figure 1(c)). These different orders represent groups of mammals such as the primates, the carnivores, the bats, or the artiodactyla (grazing animals), which in each case have evolved from a common ancestor that they do not share with species from the other groups. Knowing this, we can say that the basic relationship between brain and body size has arisen independently in each group, and this gives us confidence that it is a general feature of mammalian evolution.

This way of thinking about comparative relationships recognizes that evolution is a hierarchical process such that over evolutionary time, species evolve and give rise to daughter species, which in turn give rise to more species. Darwin called this 'decent with modification,' and the collection of such ancestral–descendant relationships it gives rise to is described by a phylogenetic tree. Figure 1(a) presents such a tree for the mammals, showing how all mammals derive from a common ancestor that might have lived about 165 Ma. Mammalian evolution then proceeded through a series of branching points that eventually gave rise to the modern day orders of mammals and eventually to the contemporary mammal species. At each branching point, all of the descendant species descend from a common ancestor that lived at that point. As we come up to the present, pairs of closely related species – such as two primates – will have shared nearly all of their evolutionary history, while pairs of distantly related species – such as a rodent and a primate – will have shared far less.

The statistical methods that together define the field of comparative methods seek to identify independent instances of comparative trends such as in Figure 1(c), and to do this must account for the shared evolutionary histories that the phylogenetic relationships imply. This is what distinguishes the phylogenetic comparative method from conventional statistics. To do this, comparative methods explicitly incorporate information about the phylogeny into their statistical tests.

Most comparative studies involve one or both of two broad classes of data, and these different kinds of data often require different statistical models. *Continuously varying traits*, as their name suggests, can adopt a range of values along a continuously varying scale. Brain size, height, lifespan, running speed, and gestation length are all continuously varying traits. *Discrete traits*, on the other hand, can adopt only a finite number of different states, and they need not be ordered in any way. Common discrete characters include such things as mating systems (monogamy, polygyny, polyandry) or perhaps nesting types (e.g., on the ground, in a tree, or in a hole).

Continuously Varying Traits

Species traits such as brain size, body size, generation time, and weaning age are 'continuous' or 'continuously varying traits.' Since the late 1990s, continuous data have been studied using a statistical technique known as *generalized least squares* or *GLS* (Garland, 2000; Schluter et al., 1997; Martins and Hansen, 1997; Pagel, 1997, 1999). The GLS approach for studying the evolution of continuous traits directly takes into account the phylogeny of a group of organisms and has superseded the earlier 'independent contrasts' approach (Harvey and Pagel, 1991; Pagel, 1993; Felsenstein, 1985). The latter is a computationally efficient method proposed to account for shared ancestry in comparative studies, but is not as flexible as GLS methods.

The Generalized Least Squares Approach

The GLS statistic models the evolution of continuous traits by assuming they have evolved by a process known as a *random walk*. The model assumes that traits evolve by some random amount in each of many short instants of time. At each instant of time, the change can be positive (e.g., the trait gets larger) or negative. The successive random changes to a trait are independent of each other and they are assumed to have a mean or average of zero and some degree of variability, known as the variance. If the observed differences across species are large, then this variance is also assumed to be large; if the variance is low (all species in the group have a similar trait value), then the variance is assumed to be low. In practice, the value of this variance is one of the parameters the GLS model estimates, and it can be viewed as the evolutionary rate of change for a trait (Schluter et al., 1997).

The GLS model uses this basic random walk process to describe the observed data on a phylogeny, such as the spread of brain sizes among a group of species. Because changes along the phylogeny are presumed to unfold independently at each instant of time and along each of the branches of the phylogeny, the phylogeny itself specifies how much a given species' trait value is expected to vary were evolution to be rerun, and how similar any pair of species is expected to be.

Thinking of evolution as ideally described by a random walk provides another and equivalent way of understanding why phylogenies are vital to comparative studies. Closely related species on a phylogenetic tree will have shared many of the same environments throughout their histories. If evolution is normally a slow and gradual process, then we expect closely related species on a phylogeny will tend to be similar. For example, lions

and tigers have shared all of their evolutionary history up to around 4 Ma – indeed they were the same species until that point.

Now, if we are trying to understand why some feature of an organism has evolved – such as its size, shape, or behaviors – then two closely related species will tend to share many of the potential explanations for that particular feature. For example, the plot of brain and body size data (Figure 1(b)) shows that the primates (dark blue) all tend to have large brains given the size of their bodies. If we want to understand why, the explanation could reside in just about any of the very many traits that all primates share by virtue of having all evolved relatively recently from a common ancestor. Comparative methods, by taking the underlying phylogeny into account, allow us to test ideas having removed the effects of shared evolutionary history.

Historically, the parameters of the GLS model were, and often still are, estimated by the method of maximum likelihood, but since around the beginning of this century Bayesian Markov chain Monte Carlo estimation procedures have become increasingly popular (e.g., Venditti et al., 2011). These methods do not just estimate the most probable value of some parameter, they also estimate the statistical uncertainty surrounding that estimate.

GLS Regression

Mammal Brain and Body Size

Researchers may be interested in studying the association between a continuous dependent (or response) variable and one or more independent (or explanatory) variables. In the case where there is one independent variable, this is called simple regression; where there is more than one it is called multiple regression. The evolution of mammalian brain size provides a good example of the use of the GLS regression approach to analyze comparative data. Theories of the evolution of mammalian brain size link brain volume to body mass either through body surface area or through basal metabolic rate. The 'body surface area' hypothesis supposes that brains must get larger in larger bodies to keep track of the increased number of inputs from the environment, and this predicts that the slope of the line relating brain volume to body mass is 2/3. The metabolic rate hypothesis predicts that the size of the brain is limited by the animals' metabolic turnover. This hypothesis can be shown to predict a slope of brain volume against body mass of 3/4.

Applied to the data of Figure 1(b) and the phylogeny of the mammals shown in Figure 1(a), the GLS model can be used to estimate the regression coefficient (or slope) relating brain size to body size, in addition to the variances of brain size that is explained by body size. Here the model returns a slope relating brain mass to body mass of 0.60, meaning that brain size does indeed increase more slowly than body size over evolutionary time as the theories predict. However, this slope is lower than the expected 2/3 to 3/4, despite a very strong correlation between the two traits. For this sample of mammals, the 95% confidence intervals around the estimated slope of 0.60 exclude both 3/4and 2/3.

Intuitively one might expect the brain–body size relationship to be more complex than a single slope implies, especially across a large ecologically diverse group of animals such as the mammals. Indeed using a different methodology, Pagel and Harvey (1989) showed that the nature (or slope) of the relationship changes between lower taxonomic groups in the mammals. If one constructs a GLS model that allows slopes (and y-axis intercepts) to vary between the orders of mammals (Figure 1(c)), we can see that the slopes vary from 0.50 in the Didelphimorphia (opossums) to 0.79 in the Chiroptera (bats), with primates being the second highest at 0.65.

Ancestral State Reconstruction and Phylogenetic Prediction

One of the more intriguing applications of comparative methods is to try to use the phylogeny in combination with information on the contemporary species to make guesses about what species were like in the past, or even to make predictions about the values of species' traits. Both approaches rely on the fact that the comparative method builds statistical descriptions or models of how evolution has progressed. It can then use that model to derive predictions.

In the case of ancestral states, in effect, what the methods do is rewind the statistical description of evolution to arrive at past or 'ancestral' states. For example, we can use the GLS model fitted to the mammals data to estimate that the ancestral brain and body size of mammals – the common ancestor to all of them that lived about 165 Ma – was 3.50 g and 0.31 kg, respectively. These are our best guesses as to what we think the ancestor was like, given our GLS model of evolution and the phylogenetic tree. One can use the same approach to reconstruct the size at any internal node of the phylogeny.

Phylogenetic Prediction: Dinosaur Genome Size

The genome size of birds is small in comparison with other amniote groups. Birds achieve this small genome by having a reduced number of repetitive genetic elements and less noncoding DNA – these genetic sequences do not code for proteins and are sometimes referred to as 'junk' DNA. It has been argued that large genomes are metabolically costly and so birds have evolved smaller genomes as a key innovation that made it easier to evolve or cope with the energetic demands of flight.

The difficulty with testing this idea is that birds trace their ancestry into the dinosaur lineage, but we have no way of knowing how big dinosaurs' genomes were because DNA does not fossilize. On the other hand, if we could find something correlated with genome size in modern animals, we might be able to use this relationship to predict the size of dinosaurs' genomes.

Organ et al. (2007) used the fact that animals with larger genomes tend also to have larger cells than animals whose genomes are smaller. To exploit this relationship, these authors first derived a GLS model relating cell size to genome size in a wide range of animals including the birds. They were then able to extract information on cell size in dinosaurs because, remarkably, fossilized bones preserve the size of individual cells. They then used the combination of the model relating cell size to genome size, along with the information on dinosaur cell size to make predictions about the unknown – and unknowable – dinosaur genome sizes.

The results of these analyses showed that the small genome size associated with present-day birds evolved millions of years prior to the evolution of birds themselves (see Figure 2).

Figure 2 Broad scale amniote phylogeny that includes some extinct dinosaur species. The branches of the tree are colored according to the inferred genome size. This shows that small genomes arose millions of years before the origin of birds.

These results cast doubt on the idea that small genomes evolved to become smaller as an adaptation in response to the energetic costs of flight.

Phylogenetic Prediction: Feeding Time and the Evolution of Food Processing

Recently, phylogenetic predictions have been used in a new and interesting way – to help decide if a trait in a species is so different from what we expect as to be classified as an 'outlier.' Imagine if you believed that one species in a group was exceptional in the evolution of a particular trait. For instance, human brain size is very large – the largest for its size of any animal. To test whether we are truly outliers, though, one could construct a model of evolution (a GLS regression model in this case) for the relationship between brain and body size in mammals excluding humans. From this model it is possible to predict the brain size of humans for our body size. If the predictions are significantly smaller or larger (more likely smaller in this case) than the actual or observed trait value, then that species can be regarded as a phylogenetic outlier.

Organ et al. (2011) used this 'outlier' test logic to try to pinpoint when cooking first evolved in the hominins (*Homo*, and other members of the human clade after the split from the chimpanzees). They constructed a model relating the amount of time spent feeding each day to molar size, on the assumption that cooking, by making foods easier to process, may be associated with a small molar size and reduced time spent feeding. They then used their model to predict the amount of time spent feeding for

humans (Figure 3(a)), comparing that to the known value for our species. As expected, humans spend significantly less time feeding than predicted for a primate of their size, and we have small molars.

Hominin molars are well preserved in the fossil record and so it is possible to reconstruct where along the human lineage a significant reduction in molar size first occurred. Organ et al. (2011) found that molar size was significantly reduced in *Homo sapiens* and *Homo erectus* but not in any other hominin species. This might suggest that cooking or food processing in some form first arose in the common ancestor of *H. sapiens* and *H. erectus*, some 2 Ma (Figure 3(b)).

Phylogenetic Signal

In our description of the random walk, we stated that if evolution is normally a gradual homogeneous process, then the phylogeny predicts that closely related species will be similar.

Figure 3 Feeding time in humans and the evolution of reduced molar size. (a) Shows a posterior distribution of predictions of percentage of the day spent feeding for humans. Note that the scale is logit transformed as feeding time is a percentage – this is a commonly used statistical transformation for percentages that ensures the data conform to the statistical assumption of the model. The arrow points to the actual or observed feeding time of humans – humans are a phylogenetic outlier; (b) A phylogenetic tree of hominins, including extinct species. The branches highlighted in red are those species that have undergone a significant reduction in molar size. This suggest that this reduction occurred in the common ancestor between *H. erectus* and *H. sapiens*.

But just how similar? We can imagine that for some traits even closely related species could appear quite different.

The extent to which species' similarities conform to what we expect given the phylogeny and the GLS random walk model is sometimes referred to as 'phylogenetic signal.' An important advantage of the GLS method is that it is possible to estimate the phylogenetic signal in the dataset under investigation, and then to adjust the analysis if this signal departs from expectation.

Pagel (1997, 1999) introduced a measure of phylogenetic signal, λ, which has become a routine part of comparative studies. The parameter λ varies between 0 and 1, where a 1 means the trait evolves as we would predict from the GLS model, but a zero means that the trait or traits evolve independently of the phylogenetic relationships among species. In this latter case, statistically accounting for the shared ancestry as implied by a phylogenetic tree may not be necessary.

The parameter λ should be simultaneously estimated along with other parameters in analyses to capture the historical trace of phylogenetic signal that is present in the data. This ensures that the phylogenetic contribution to the outcome is not under- or overemphasized. Some characteristics such as body size and metabolic rate have very strong phylogenetic signal. We expect other traits that might be ecological or behavioral, such as range size, feeding time, or parasite density, to have some phylogenetic signal, but that signal may not be as strong.

Other methods to detect phylogenetic signal have been proposed, including Blomberg et al.'s (2003) *K*, Abouheif's (1999) C_{mean}, and Moran's (Moran, 1950; Gittleman and Kot, 1990) *I*. A recent simulation study that examined these four most commonly used indices of phylogenetic signal (Münkemüller et al., 2012) showed that λ is the most robust measure.

Discrete Traits

The Continuous-Time Markov-Transition Process

The Markov-transition model provides a natural framework to analyze data that can adopt only a small number of distinct states (Pagel, 1994). Applied to a phylogenetic setting, the Markov approach estimates the rates at which a trait or character makes transitions among its possible states as it evolves over time along the branches of a phylogeny.

For a trait that can take only two values (e.g., 0 or 1), two rates must be estimated, one for transition from '0' to '1,' and the other for transitions from '1' to '0.' Conventionally, we assign 0 to the absence of the trait and 1 to its presence. Then, intuitively, if transitions from $0 \rightarrow 1$ proceed at a higher rate than transitions from $1 \rightarrow 0$, and if both processes are allowed to unfold along the branches of a phylogeny, then we expect to see more species with than without the trait. The continuous-time Markov model examines this distribution of 0's and 1's along with the phylogeny, and then estimates the transition rates that best explain the species' values.

The model easily generalizes to a trait with more than two values. Imagine a trait can take one of three states – 0,1, and 2 – such as might be used to categorize species into omnivores, herbivores, and carnivores. In this case, six transition rates are required to specify the 'forward' and 'backward' transitions among the three possible pairs of states. Figure 4 shows an example of a trait with four values, requiring 12 transition rates.

In addition to studying the evolution of single traits, the Markov-transition model can be used to study whether two discrete traits are coevolving. Consider two binary traits, each one of which can adopt a 0 or a 1. Then, if we consider all possible pairings of these two traits, there are four possible outcomes (0,0; 0,1; 1,0; 1,1). If we imagine we are interested in the hypothesis that when one of the states changes to a 1 the other one does as well (they change in a correlated fashion), then we expect a preponderance of species that are either in state (0,0) or (1,1).

The Markov transition model examines these states along with the phylogeny, and then constructs a model to describe their evolution. This model describes all possible transitions among the four sets of paired states. In practice, it can be shown that eight parameters are sufficient to calculate the probability of any kind of change in any branch of the tree. The method then compares the goodness of fit of this model allowing correlated evolution to the goodness of fit of a model in which the two traits evolve independently on the tree.

These principles can be applied to study the correlated evolution of traits with more than two (binary) values. However, in this situation the number of parameters or transition rates that need to be estimated usually makes this prohibitive.

The Evolution of Political Complexity

When applied to a single trait such as in these examples, the model not only estimates rates of change but can be used – as we saw with the GLS model – to estimate probable ancestral states. Political complexity varies among human cultures. Much of the Western world is dominated by states – defined by a centralized bureaucratic system that oversees specialized administrative offices – but acephalous societies (which lack political hierarchies) are widespread throughout the world. The evolutionary sequence from simple to complex societies is much debated. Do changes occur in small incremental steps or are there large nonsequential leaps? One can use the Markov approach described earlier to study this.

Currie et al. (2010) studied the evolution of political complexity in 84 Austronesian societies. A phylogenetic tree describing how these cultures are related to each other can be

Figure 4 The estimated rate parameters for transitions between different forms of political structure. The thickness of the arrows is proportional to the estimated value of the associated transition rate. Thick lines mean high rates; dotted lines are rate that are indistinguishable from zero.

inferred from linguistic data (similarities and differences among languages or dialects); such trees are analogous to species phylogenies. The authors define levels of political complexity by the number of hierarchical decision-making levels; these are congruent with traditional social evolutionary classifications: societies lacking permanent leadership beyond the local community are called 'acephalous'; those with a single level beyond the local community are named 'simple chiefdoms'; those with two levels represent 'complex chiefdoms'; and societies with more than two levels are 'states.' They estimated the Markov transition rates between these states along the branches of the phylogenetic tree of cultures derived from language data.

Figure 4 provides a summary of the results. Political complexity always seems to accumulate from simple to more complex forms in a series of small sequential steps. By comparison, complexity can be lost in larger steps and even all at once. This study was the first to apply quantitative statistical methods to the study of the evolution of political complexity and it provide some interesting support for the idea that cultural evolution, like biological evolution, is most likely to occur via small incremental steps.

Genotypic Sex Determination and Adaptive Radiations in the Sea

The same logic that we applied to continuous traits in terms of phylogenetic prediction can be applied here for discrete traits that are correlated. If two discrete traits are associated, it is possible to predict the state of a species for which the value of some trait is not known. An example of this is the sex determination mechanism for extinct marine reptiles.

Sex determination mechanisms in reptiles can be broadly split into two categories. The first of these is genotypic sex determination, similar to what is seen in birds or mammal. The second is temperature-dependent sex determination – here the environmental temperature at some critical period of embryonic development determines the sex of an individual.

Sex determination mechanism of a species has been linked to life history and ecology but never to adaptive radiations, which are often associated with key innovations. Sex determination mechanism has the potential to be important in radiations of marine vertebrates, and the relatively stable temperature of the sea makes temperature determination problematic.

Organ et al. (2009) collected sex determination data (genetic or temperature determined) and data on whether a species bears live young (is viviparous) or lays eggs (is oviparous) for 94 vertebrate species. Using these data, they found a significant correlation between these two discrete traits. Figure 5 shows the evolutionary transition rates between sex determination and whether or not a species bears live young.

The fossil record shows that some marine reptiles (mosasaurs, sauropterygians, and ichthyosaurs) gave birth to live young (see Figure 3 in Organ et al., 2009). This information is used in conjunction with the model of correlated evolution in Figure 5 and the phylogenetic position of the species, to infer the mode of sex determination. Organ et al. (2009) showed that all these extinct lineages had a high likelihood of using genotypic sex determination.

These results mean that genotypic sex determination is present in all known fully marine vertebrate groups and support the idea that genotypic sex determination in a key innovation in producing adaptive radiations in marine environments.

Figure 5 The evolutionary transition rates between sex-determining mechanism and reproductive mode in extant amniote species. The thickness of the arrows is proportional to the estimated value of the associated transition rate. Thick lines mean high rates; dotted lines are rate that are indistinguishable from zero. (S.D. = sex determination.)

New Developments

Researchers may be interested in investigating some evolutionary scenarios or hypothesis tests for which widely used and established comparative methods are not sufficiently developed. For example, an important distinction in the study of continuously varying traits is that between *measures* (like the traits discussed previously) and *counts*. Although these two categories may seem intuitively similar they have different statistical properties and should be treated differently in comparative studies. Many researchers attempt simple mathematical transformations of count data to make them behave more like measured data – the logarithmic transformation of count data is widely used – but this transformation can introduce biases into hypothesis tests. Rather, count data should be studied using models based on Poisson distributions (or negative binomial distributions) instead (see O'Hara and Kotze, 2010 for more details).

Another example is that researchers might be interested in studying the evolution of a binary discrete dependent variable in a regression, to ask whether the probability of being in one state or other is associated with other characteristics (continuous and discrete). For example, one might wish to investigate what ecological or life history variables explain the presence or absence of belly patches (sexual display) in phrynosomatid lizards. Such analyses can be done via logistic (Ives and Garland, 2010) or probit regression (de Villemereuil et al., 2012).

More recently, phylogenetic generalized linear models and phylogenetic generalized linear mixed models have been proposed (Ives and Helmus, 2011; Hadfield, 2010) for use when the variable to be predicted – the dependent variable – is based on counts or is a binary discrete trait in a phylogenetic context. These methods are in their infancy and are not currently widely used by the phylogenetic community. However, these will almost

certainly form the bases of a new generation of phylogenetic comparative methods for the future.

General Discussion

Comparative methods remain a popular set of techniques for investigating adaptation and the evolutionary process. New statistical approaches are easy to use and make use of more of the information in the data than previous methods. Coupled with increasingly accurate and informative phylogenies based upon genomic information and the fossil record, comparative methods can be used to test new hypotheses and to reexamine old ones.

Here we have discussed the application of comparative methods to study the evolution of traits or characteristics of species, as well as in one case the evolution of human societies. In addition to such applications, entire areas of comparative methods are devoted to using phylogenetic information to study speciation and extinction rates (see Nee, 2006; Ricklefs, 2007; Maddison et al., 2007; Venditti et al., 2010).

Abstract

The comparative method, the most important technique in historical linguistics, is explained, together with its basic assumptions and limitations. The comparative method compares related languages in order to reconstruct the ancestral language from which they descend; thus it serves to show that languages are related, the basis of linguistic classification. The questions of how realistic its reconstructions are and how far back in time they can reach are considered.

The comparative method is the most important of the various techniques used to recover linguistic history. It is a method (or a set of procedures) which compares related languages, descendants from a common ancestral language, in order to postulate, to 'reconstruct,' the ancestral language. It is commonly considered a major event in the history of ideas; inspired by the success of the comparative method in linguistics, numerous other disciplines in the nineteenth century adopted comparative methods of their own. In this article the comparative method is explained and its basic assumptions and limitations are considered.

The comparative method is the most important of the various techniques used to recover linguistic history. It is a method (or a set of procedures) which compares related languages, descendants from a common ancestral language, in order to postulate, to 'reconstruct,' the ancestral language. It is commonly considered a major event in the history of ideas; inspired by the success of the comparative method in linguistics, numerous other disciplines in the nineteenth century adopted comparative methods of their own. In this article the comparative method is explained and its basic assumptions and limitations are considered.

The Comparative Method and Language Families

Language which belong to the same family are said to be genetically related – this means that they derive from a single ancestral language, called a proto-language. Genetic relationships among languages are talked about in genealogical terms: 'sister languages,' 'daughter languages,' 'parent language,' and 'language families' (definitions below). Through linguistic changes, dialects develop in a language, and then as further changes accumulate in time, these dialects become distinct languages, related to one another ('sister languages') and descendants ('daughters') of the original language (the parent or proto-language). By applying the comparative method to related languages which descend from an original ancestor language, linguists postulate what that proto-language was like – that is, they reconstruct that language. For example, a comparison of English with its relatives, Dutch, German, Danish, Swedish, Icelandic, and so on, reveals what the proto-language, in this case called 'Proto-Germanic,' was like. Thus, English is, in effect, a much changed 'dialect' of Proto-Germanic, having undergone successive linguistic changes to make it what it is today, a different language from Swedish and German and its other sisters, each of which underwent different changes of their own. Therefore, every proto-language was once a real language regardless of whether it is successfully reconstructed or not, and all languages which have relatives have a history which classifies them in language families.

The aim ofthe comparative method is to reconstruct as much as possible of the proto-language by comparing its daughter languages (the related descendant languages), and to determine what changes they underwent as they diversified from their common ancestor. The comparative method serves two purposes: to show that languages are related, and to reconstruct as much as possible of the parent language. If reconstruction is successful, it shows that the initial assumption that the languages are related was warranted, and it reveals the nature ofthe proto-language.

Of course, success is dependent upon the extent to which evidence of the original traits is preserved in the descendant (daughter) languages and upon how astute the linguist is at applying the comparative method to them. For example, by comparing Romance languages (Spanish, Portuguese, French, Italian, etc.), the linguist reconstructs Proto-Romance; Proto-Romance is equivalent to the spoken language at the time Latin began to split up into its descendants. If successful, what is reconstructed for Proto-Romance by the comparative method should coincide with the Proto-Romance which was actually spoken at the time before it split up into its daughter languages. In this case, since Latin is abundantly documented, it is possible to check to see whether what is reconstructed by the comparative method accurately approximates the spoken Latin that is known from written sources at that time. However, the possibility of checking reconstructions in this way is not available for most language families, for whose proto-languages there are no written records. For example, for Proto-Germanic (from which English, German, Swedish, etc. descend), there are no written records, and this language is known only from comparative reconstruction.

Often attempts to show that languages are genetically related or to reconstruct a proto-language begin with recognition of similarities among the languages being compared. However, similarities among languages can be due to a number of things, for example to borrowing, accident, onomatopoeia, etc., in addition to inheritance from a common ancestor (see Campbell, 1998: pp. 311–326). Therefore, to show languages are related or to reconstruct successfully, similarities which are explained by factors other than common inheritance need to be

avoided. The comparative method, aided by regular sound correspondences, helps to eliminate these factors.

Application of the Comparative Method

To be able to apply the comparative method, one needs to know some technical terms

Proto-language. (1) The once spoken ancestral language from which daughter languages descend; (2) the language reconstructed by the comparative method which represents the ancestral language from which the compared languages descend. (To the extent that the reconstruction is accurate and complete, (1) and (2) should match.)

Sister language. Languages which are related to one another by virtue of having descended from the same common ancestor (proto-language) are sisters; that is, languages which belong to the same family are sisters to one another.

Cognate. A word which is related to a word in sister languages by reason of these forms having been inherited by these sister languages from a common word of the proto-language from which the sister languages descend.

Cognate set. The set of words which are related to one another in the sister languages because they are inherited and descend from a single word of the proto-language.

Sound correspondence. In effect, a set of 'cognate' sounds; the sounds found in the related words of cognate sets which correspond among related languages because they descend from a common ancestral sound. (A sound correspondence is assumed to recur in various cognate sets.)

Reflex. The descendant in a daughter language of a sound of the proto is said to be a reflex of that original sound; the original sound of the proto-language is said to be reflected by the sound which descends from it in a daughter language (cf Campbell, 1998: p. 112).

In the application of the comparative method, first potential cognates among related languages (or among languages for which there is reason to suspect related-ness) are sought. It is convenient to begin with cognates from 'basic vocabulary' (body parts, close kinship terms, low numbers, common geographical terms), since these tend not to be borrowed from other languages. Ultimately, it is the systematic sound correspondences discovered in the application of the comparative method which demonstrate which are true cognates. Words which are similar due to accident, borrowing, and other non-genetic factors usually do not exhibit the recurring sound correspondences that true cognates do. Some cognates from Greek, Latin, and English (members of the Indo-European family of languages) are illustrated in Table 1.

Next, the sound correspondences are sought. For example, in the cognates of Table 1, the first sound in each of the cognate sets exhibits the sound correspondence.

Greek *p*, Latin *p*, English *f*.

Table 1 Indo-European cognates.

Greek	*Latin*	*English*	
pod-	ped-	foot	'foot'
pater	pater	father	'father'

Since the sound correspondence recurs in these (and many other) cognate sets, it is unlikely that it could come about by sheer accident.

When the sound correspondences have been determined, the next step is to reconstruct the original sound. Linguists postulate what the original sound in the proto-language most likely was based on the phonetic properties of the sounds in the daughter languages as represented in the sound correspondence set. General guidelines help determine the most realistic reconstruction. For one, the known direction of certain sound changes is a valuable clue. For example, many languages have changed *p* to *f*, but change in the other direction, *f* to *p*, is extremely rare. In this case, it is said that the expected direction is *p* to *f* (and not *f* to *p*). This being the case, for the sound correspondence of Greek *p*-, Latin *p*-, English *f*-, **p* is reconstructed, since a change **p* to *f*, which would be necessary to derive the English reflex of *f*, is in an expected direction. (Note that the asterisk, as here with **p*, symbolizes reconstructed things.) If **f* were postulated for the proto-sound from which this sound correspondence descended, it would be necessary to assume the change of **f* to *p* in Greek and Latin, a change which goes against the expected directionality. Therefore, **p* is reconstructed in this case, together with the assumption that English underwent the common sound change of **p* to *f*.

Another guideline is the principle of 'majority wins': unless there is evidence to the contrary, for the proto-sound one reconstructs a sound coinciding with the particular sound in the correspondence set which is found in the greatest number of daughter languages. In this example, since *p* is found in both Greek and Latin, but *f* is only in English, 'majority wins' selects **p* for the reconstruction. Common sense is behind this; it is less likely that the same change (here **f* to *p*) would take place independently several times (here in Greek and in Latin) than that a single change would take place only once (**p* to *f*, only in English). The interpretation of the majority, however, can be complicated, requiring caution in the application of 'majority wins.'

This process of reconstructing sounds for the various correspondence sets is repeated until all the sounds of the proto-language have been reconstructed and the changes in the daughter languages worked out.

When all the proto-sounds have been reconstructed, it is possible to reconstruct words of the proto-language. For example, in the cognate set Greek *pod*, Latin *ped*, English *foot* 'foot,' **p* has already been reconstructed as the first sound of this word in the proto-language, based on thep-, *p*-,*f*- correspondence set just considered. For the second sound (*o*, *e*, *oo*), **e* is reconstructed on evidence not available in this short example; the correspondences for the vowel are complicated. For the last sound of the word, evidence from other cognate sets shows that the sound correspondence, Greek *d*, Latin *d*, English *t*, recurs and that the best reconstruction for this sound is *t. Putting these reconstructed sounds together, **p* for the first sound, **e* for the second, and **d* for the third, gives the reconstruction **ped* 'foot,' a word in the proto-language. In this way the vocabulary of the proto-language can be recovered.

The reconstruction of a sound, a word, or large portions of a proto-language is, in effect, a hypothesis (actually a set of interconnected hypotheses) concerning what those aspects of the proto-language must have been like. Hypothesized

reconstructions can be tested; sometimes they prove wrong; sometimes they must be modified, based on new insights. These insights may involve new interpretations of the data already on hand or new information that may come to light. The discovery of a previously unknown language may provide new evidence, a different testimony of the historical events which transpired between the proto-language and its descendants, which can change how parts of the proto-language are viewed. For example, with the discovery and decipherment of Hittite (and other languages of the Anatolian branch of Indo-European), the whole picture of Proto-Indo-European phonology changed.

There are numerous general treatments of the comparative method; for some of the clearer accounts, *see* Anttila (1989), Arlotto (1981), Campbell (1998), Crowley (1997), Hock and Joseph (1996), and Trask (1996).

Assumptions and Limitations of the Comparative Method

There are limitations on what can be recovered of a proto-language via the comparative method. Traditionally, some of these limitations are called 'assumptions,' since they are inherent consequences of how the comparative method is structured and how it is applied.

There are four main 'assumptions'

(1) The proto-language was uniform, with no dialects or variation.

Clearly this 'assumption' is unrealistic, since all known languages have regional or social variation, different styles, and so on. However, it is not so much that the comparative method 'assumes' no variation; rather, it is just that there is nothing built into the comparative method which would allow it to address variation directly. This means that what is reconstructed will not recover the once spoken proto-language in its entirety, that is, with all its variation. Still, rather than stressing what is missing, linguists are happy that the method provides the means for recovering as much of the original language as it does. This assumption of uniformity is a reasonable idealization; it does no more damage to understanding of the proto-language than, say, modern reference grammars do which concentrate on a language's general structure, typically leaving out consideration of regional, social, and stylistic variation. Moreover, dialectal variation is not always left out, since in some cases scholars do reconstruct dialect differences to the proto-language based on differences in daughter languages which are not easily reconciled with a single uniform starting point.

Assumptions (2) and (3) are related:

(2) Language splits are sudden.
(3) After the split up of the proto-language, there is no subsequent contact among the related languages.

These assumptions are a consequence of the fact that the comparative method addresses directly only material in the related languages which is inherited from the proto-language and has no means of its own for dealing with borrowings, the results of subsequent contact after diversification into related languages. Borrowing and the effects of language contact are, however, not neglected. Rather, it is necessary to call upon other techniques which are not formally part of the comparative method for dealing with borrowing and the results of language contact. It is true that the comparative method contains no means for addressing whether a language gradually diverged over a long period of time before ultimately distinct but related languages emerged, or whether a sudden division took place with no subsequent contact between the parts of the original language community. Usually, however, reconstruction by the comparative method is reasonably successful, regardless of how slow or sudden the split up of the proto-language may have been.

(4) Sound change is regular.

This assumption is true; it is not a limitation, but an asset, extremely valuable to the application of the comparative method. For example, in the example above, Proto-Indo-European *p regularly changed to f in English in all the words of this kind which formerly contained a *p. Knowing that a given sound in given circumstances changes in a regular fashion permits reconstruction of what the sound was like in the parent language. If a sound could change in arbitrary, unpredictable ways, it would not be possible to determine from a given sound in a daughter language what it may have been in the parent language, and, for a particular sound of the parent language, it would not be possible to determine what its reflexes in its daughter languages would be. If, for example, an original *p of the proto-language could arbitrarily for no predictable reason become f in some words, γ in others, k in still others, and so on, then it would not be possible to reconstruct it. In such a situation, comparing, say a p of one language with a p of another related language would be of no avail, if the p in each could have come in unpredictable ways from a number of different proto-sounds.

How Realistic Are Reconstructed Proto-Languages?

The success of any given reconstruction depends on the material at hand with which to work, and the ability of the comparative linguist to figure out what happened in the history of the languages being compared. In cases where the daughter languages preserve clear evidence of what the parent language had, a reconstruction can be very successful, matching closely the actual spoken ancestral language from which the compared daughters descend. However, there are many cases in which all the daughter languages lose formerly contrasting sounds and lose grammatical categories through changes of various sorts. It is not possible to recover via the comparative method things in the proto-language if the daughters simply do not preserve evidence of them. In cases where the evidence is severely limited or unclear, reconstruction often results in omissions or mistakes. The comparative linguist makes the best inferences possible, based on the evidence available and on everything known about the nature of human languages and linguistic change. It is necessary to make the most of what is available to work with. Often the results are very good; sometimes they are incomplete, occasionally wrong. In general, the longer in the past the

proto-language split up and the more linguistic changes that have taken place in the daughter languages, the more difficult it becomes to reconstruct with full success.

A comparison of reconstructed Proto-Romance with attested Latin provides a telling example. It is possible successfully to recover a great deal of formerly spoken Proto-Romance via the comparative method. However, the modern Romance languages for the most part preserve little of the former noun cases and complex verb inflections which Latin had. Subsequent changes have obscured these aspects of the grammar so much that large parts of Proto-Romance are not reconstructible by the comparative method. On the other hand, a great deal of Proto-Romance is recoverable.

An area of speculation and controversy concerns the outer limits of the comparative method. That is, is there a recognizable time depth beyond which the comparative method ceases to be effective? Some suggest that the comparative method cannot reach beyond the oldest currently reconstructed proto-languages; this cut-off date beyond which the comparative method is assumed not to be able to reach is variously speculated to be 6000, 8000, or 10 000 years. Since there is no reliable means of dating languages splits, these dates are rough guesses. The true issue is not really about dates at all, but rather about how much evidence related languages preserve upon which to base a reliable reconstruction. Typically, languages separated by many millennia have had longer in which to undergo changes, making them more different from one another than languages separated only by a few 100 years. Languages which have undergone many changes conceivably could preserve little of their original vocabulary or grammar; however, at the same time, it is also possible for a language to undergo relatively little change over relatively long periods. Thus, the upper limit of the comparative method is a function of whether accumulated changes have obliterated evidence in related languages, and not directly a matter of how long they have been separated.

Abstract

During the second half of the twentieth century, the globalization movement transformed the nature of comparative research in education. The United Nations Organization and its agency UNESCO, promoting cooperation among nations through education, science, and culture, led this development through 'Education for All' and the integration of organizational, international, comparative, and global approaches to education. The conduct of educational research worldwide has been greatly influenced by the International Association for the Evaluation of Educational Achievement through the monitoring of educational outcomes and the introduction of systemic and modeling approaches to research in education leading to evidence-based making of educational policy.

Introduction

Comparative research in education is closely related to the field of comparative education. However, this field has been extended and greatly restructured by the movements that have operated during the second half of the twentieth century and the first decade of the twenty-first century involving initially internationalization and more recently globalization. The introduction of a worldwide program by the United Nations Educational Scientific and Cultural Organization (UNESCO) of 'Education for All' (EFA) has been concerned not only with the promulgation of basic education in developing countries (*see* Affordable Private Schools in Developing Countries), but also with the advancement of education at all levels in the more developed countries. These movements have been fed and greatly strengthened not only by the findings of research in the many fields of education, and by developments in information and communications technology (ICT) but also by the many agencies of the United Nations Organization. Each of these movements of comparative education, international education, and global education, as well as the organizational and developmental programs of UNESCO have employed their own strategies of research, that appear to be historically and structurally independent and different from each other. This article considers the four different components of a field of education that has experienced remarkable growth since the end of the Second World War when the United Nations Organization was established. In addition, this article considers the many different types of inquiry and research studies in education that have been undertaken with a cross-national, comparative, and developmental perspective. As the generative example of this research activity, scholarly inquiry, and developmental endeavor, the studies conducted under the auspices of the International Association for the Evaluation of Educational Achievement (IEA) are examined from both theoretical and methodological perspectives, and the key findings of IEA studies are listed and briefly discussed. The concluding section of this article addresses the issues arising from the advancement of this field of research in education with a strongly systemic as well as a more traditional analytical approach, and considers the nature of comparative research and inquiry in the future.

Historically, comparative education has identified as its founding father Marc-Antoine Jullien (1817), whose seminal work was published in 1817, and in which he emphasized the collection of documents, objective observation, and thoroughness in recording and systematic analysis. At that time, the population of the world had barely exceeded 1 billion people. In the decade prior to the Second World War, the population of the world passed the level of 2 billion people. The world's population now exceeds the 7 billion mark. This explosion in the world's population led to a remarkable growth in formal education, that Connell (1980, p. 3) argued scarcely existed for the majority of the people in the world at the beginning of the twentieth century outside the more developed and industrialized countries of Western Europe, some British colonies, such as Australia, Canada, and New Zealand, as well as the United States. Subsequently, an expansion of tertiary education occurred and the ideas of lifelong and recurrent education were advanced, together with education for early childhood development.

The growth that has taken place in higher education during the period from 1960 onward has been reported and discussed on a global scale by Foskett and Maringe (2010, p. 307). It had been estimated that in 1960, the number of students in higher education was 13 million. It grew to 28 million by 1970, 68 million by 1991, and had exceeded 150 million by 2010. Moreover, by 2030, the student population in higher education could realistically be considered to rise to 250 million. This expansion is taking place as a result of the recognition by national governments of the need for economic and technological development in response to population growth and the necessary advancement of higher education to meet these needs.

The demand for university places in countries like China, India, Indonesia, and Malaysia now greatly exceeds the number of places available. As a consequence, there is a marked trend that involves international education for students to move from their homelands to countries where places can be found

in the institutions of higher education that are being expanded to meet the demand. Moreover, there is a similar movement at the upper secondary school level for students to move to countries where they can be educated, and can compete for entry to universities of choice. Kell and Vogl (2012) have documented the extent of transnational student mobility, particularly in the Asia-Pacific region, and have emphasized the global nature of the phenomenon.

The forces of globalization have thus reoriented the fields of comparative and international education from affording opportunities for a few privileged adults to travel in order to investigate and study how education is provided and conducted in other countries. International education now involves very large numbers of students, together with their parents, making comparative judgments about the countries in which students seeking school or higher education can best study.

Globalization and the Leadership of the United Nations

Following the end of the Second World War, the United Nations Organization was established in 1945, together with many specialist agencies, including the World Bank, the United Nations Development Program (UNDP), and the United Nations Children's Fund (UNICEF). In addition, a specialist agency was founded in 1946 to promote cooperation among nations through education, science, and culture and the promotion of peace between the countries and states of the world (Huxley, 1946) – the UNESCO. These different agencies all made the initial moves toward globalization in their specific areas of interest. While UNESCO encountered problems from time to time in the working together of its approximately 200 members, it is widely acknowledged that the forming of unity among nations is a major task that is dependent on educating the now 7 billion people living in the world. Moreover, only through programs for educating in literacy, particularly among women, can the world's population be contained, rather than distributing food and aid to those in need, or lending money to support economic advancement. In addition, the World Bank strengthens development for the reduction of poverty through microfinance programs to enable women and their families to become independent of aid. Both agencies operate within a worldwide context. These developments lead both directly and indirectly, to the advancement of globalization that is erroneously viewed by many people solely in economic terms. Giddens (1999), in discussing the *Runaway World: How Globalization is Reshaping Our Lives*, argued that globalization involved increasing social, political, and ideological interdependence among nations. Giddens (1999, p. 10) stated

> I would have no hesitation, therefore, in saying that globalisation, as we are experiencing it, is in many respects not only new, but also revolutionary. Yet, I don't believe that either the sceptics or the radicals have properly understood either what it is or its implications for us. Both groups see the phenomenon almost solely in economic terms. This is a mistake. Globalization is political, technological, and cultural as well as economic. It has been influenced above all by developments in systems of communication, dating back only to the late 1960s.

Thus, the phenomenon of globalization stands alongside comparative education and international education as a movement supported by the United Nations Organization and its agency UNESCO that has established 'global education' as a major force in today's world (*see* Globalization in Education).

A Model of Worldwide Activity in Comparative Education

Comparative education and international education now operate alongside global education and globalization at all levels of primary, secondary, higher, technological, and lifelong systems of education in all countries of the world. No longer is it appropriate to view only comparative and international education as the two sectors of a whole. The field under consideration appears to be best viewed as a tetrahedral model with four sides as is shown in Figure 1 that provides an unfolded 'net' of a three-dimensional structure.

This model is discussed in the four sections that follow with respect to the nature of the educational aspects of the worldwide activity in the traditional field of comparative education, together with the types of research that are undertaken in each specific sector. The four sides of the tetrahedral model are:

1. Organizational – with developmental and monitoring research;
2. International – with descriptive and structural research;
3. Comparative – with analytical and comparative research; and
4. Global – with systemic and modeling approaches to research.

Figure 1 An unfolded model of worldwide activity in comparative education.

The IEA has now been in operation for more than 50 years, during which it has been engaged in all four approaches to research. Consequently, its research activities can be used to illustrate what is argued to be replacing the traditional field of comparative research.

Organizational and Developmental Education

UNESCO as a worldwide organization has collected information on the provision of educational services across the world through its institutes, namely, the International Institute for Educational Planning (IIEP) in Paris, the International Bureau of Education (IBE) in Geneva, and the UNESCO Institute for Education (UIE) in Hamburg. These three institutes have also maintained a scholarly and systematic orientation in their studies of education across both the developed and developing countries of the world. Two very important publications from UNESCO, *Learning to Be: The World of Education, Today and Tomorrow* (Faure, 1972) and *Learning: The Treasure within* (Delors, 1996), have provided the bases for informed debate both within and between nations on the future of education from a world perspective. These publications emphasized the idea of lifelong learning in a world context that included both developed and developing countries in which seven tensions were operating in a world where globalization was rapidly taking place, between

1. the global and the local;
2. the universal and the individual;
3. tradition and modernity;
4. long-term and short-term considerations;
5. the need for competition and concern for equality of opportunity;
6. the extraordinary expansion of knowledge and the capacity of human beings to assimilate it; and
7. the spiritual and the material.

The monitoring of the change caused by globalization in education across the world is currently a major challenge for research in education. Only with soundly based information on the magnitude and direction of change that is provided through the use of strong and well-recognized indicators can policy making and planning lead to avoiding the major catastrophes that could be caused by the use of nuclear weapons, the population explosion, degradation of the biosphere, and widespread death from disease and famine.

The World Conference on Education for All

In 1990, a World Conference on 'Education for All' was held at Jomtien in Thailand. This conference was a turning point in the globalization of the processes of education, and was a joint initiative of four world agencies, namely, UNESCO, UNDP, UNICEF, and the World Bank. The conference did not just consider initial education and the basic skills of literacy and numeracy. It sought to achieve, by the turn of the century in the year 2000, six important targets:

1. expansion of early childhood care and development;
2. universal access to completion of primary education;
3. improvement in learning achievement;
4. increase in adult literacy rates;
5. expansion of provision of basic education and training in essential skills required by youth and adults; and
6. increased acquisition by individuals and families of the knowledge, skills, and values necessary for better living and an improved quality of life (Maclean and Vine, 2003, p. 18).

In 2000, a World Education Forum was held at Dakar in Senegal to carry out a comprehensive review of what had been achieved in the different regions of the world where UNESCO centers operated to introduce and support these objectives during the previous decade. No region of the world could claim with the necessary evidence to have achieved its goals. Nevertheless, this program of purposeful and deliberate activities, operated on a worldwide front in all the many different regions through the governmental involvement of three-quarters of the countries of the world. This was a major educational revolution since it was the first occasion on which a great majority of the nations of the world had agreed through the introduction of educational policy that the provision and nature of education would be changed through specific programs. Education was clearly recognized as the only way through which a majority of the peoples of the world both as national groups and indirectly as individuals could agree to advance the quality of life of all people who were living on planet Earth.

Research within Organized Developmental Programs

Within organized programs undertaken on a worldwide basis, the type of research activity that is considered to be required involves the introduction and the monitoring of the changes in the levels of performance of the people for whom the developmental programs are provided. This strategy of the monitoring of educational outcomes, can be linked to the systematic and regular collection of information, or can involve conducting special assessment and evaluation studies in order to obtain the necessary information, before, during, and after a planned program is conducted. The monitoring of educational outcomes is considered in greater detail in a later section.

International Education

During the early decades of the sixteenth century, Erasmus, a scholar from Rotterdam traveled between the great universities of Europe – Rome, Florence, Venice, the Sorbonne, Padua, Cambridge, and Oxford – and wrote prolifically on his conversations and from his readings (Davis, 2010). He can be said to have laid the foundations for the internationalization of education that has since flourished as the institutions of higher education have spread across the world. Today, international education in universities, academies, and centers of research extends across a wide range of activities involving learning, teaching, and scholarly publication in books, journals, and the World Wide Web. These include

1. collaborative partnerships in research,
2. exchange of students and staff between institutions and countries,
3. recruitment of international students from other countries,

4. design of curricula together with changes in content, teaching methods, objectives, and assessment procedures,
5. preparation and production of encyclopedias, books, and articles,
6. conduct of offshore teaching and learning programs, and
7. widespread use of ICT for instruction, the dissemination of information and debate on ideas and policies (Maringe, 2012, pp. 17–34).

International education has led to the establishment of equivalent standards of performance in the award and mutual recognition of qualifications with a common degree framework and a common credit transfer system not only between institutions but also between countries as is provided in the Bologna Process across Europe. Moreover, this aspect of internationalization has had an impact on school systems with the establishment of the International Baccalaureate, and the use of language proficiency tests, particularly in English-speaking countries, as well as the development of aptitude tests for use across countries for university entry.

A further outcome of international education has been the employment of a variety of schemes for the ranking of institutions, particularly between countries, on many different criteria in order to identify the quality standards and reputations of the institutions involved. Inevitably, rankings, such as those produced by the Shanghai Jiao Tong University and by the *Times Higher Education* have been used for purposes of marketing. Such rankings have covered criteria such as international orientation, student support, graduate employability, third party funding, research output in terms of scholarly publications, and higher degree graduates. However, such rankings were highly contested as the information on which they were based was argued to be inaccurate, incomplete, or inappropriate to the disciplines involved (Usher and Savino, 2007).

Descriptive Research

While the impact of international education has been very visible at the level of higher education, it has led to the collection of information on the provision and conduct of education at all levels. The IBE in Geneva has since 1933 sought to obtain and publish statistical information on education from the now approximately 200 countries and states that were members of the UNESCO. The recording of such information with an adequate degree of accuracy, meaning, and comparability across these diverse members has been a very difficult task. Nevertheless, the *International Year-Book of Education* has served a useful purpose, particularly among the developing countries. The Organisation for Economic Cooperation and Development (OECD) has also undertaken the collection of similar statistical information from among its member countries that led to the production of *Education at a Glance*.

Comparative Education

The field of comparative education was established formally in the early decades of the nineteenth century and was advanced by the reports of Matthew Arnold and the writings of Emile Durkheim. It developed rapidly in the twentieth century with the greater ease of travel and communication and the rapid expansion of formal education at all levels. Courses on comparative education were introduced in universities, particularly in the United States and Great Britain. It was recognized that in this field of inquiry both descriptive and historical studies were inadequate. Furthermore, it was acknowledged that (1) attention solely to processes and not products; (2) the examination of qualities and the failure to consider quantities; (3) the restriction of investigation to single disciplinary areas, and the ignoring of an interdisciplinary strategy as well as policy-oriented issues; and (4) the use of a single method of inquiry, a so-called scientific method, were to overlook the variety and richness of the field. Thus, Kandel (1933) sought to ascribe the developments that occurred in education within a particular country to national character, and Mallinson (1957) contended that a so-called mental constitution influenced educational development within a country. However, Hans (1949) moved to a higher level of generality by identifying specific factors that influenced educational development, namely, (1) religious factors; (2) secular factors, such as humanism, socialism, nationalism, and democratic ideals; and (3) national factors, such as location, size, language, ethnicity, culture, economy and population. It could also be argued that the powerful ideas arising from the Darwinian concept of evolution influenced the drive for schooling in which children could learn to read, write, and count and contribute as adults to life in a modern industrial society (Connell, 1980) (*see* Evolutionary Approach to Education Science). Likewise, Karl Marx's ideas influenced educational policies and practices in a substantial section of the world, including, in particular, the former Soviet Union and China.

Analytical Research: Relationships, Processes, and Products

The complexity of the field of comparative education that includes (1) many disciplinary areas ranging across philosophy, history, sociology, demography, psychology, politics, economics, the sciences, and mathematics, to name only a few; (2) many levels of operation, involving the system, district, school, classroom, student, peer group, and home; and (3) many factors associated with the characteristics of the individual and the institution, as well as the country and region of the world present a major challenge to researchers and scholars. Moreover, education is primarily concerned with learning and development that necessarily involves the examination of change over time. Longitudinal studies operating at different levels are replacing cross-sectional studies that are associated with a specific point in time. Consequently, descriptive studies are being replaced by investigations that examine relationships, the operation of processes, and the generation over time of identifiable and measurable trends in outcomes and products. Fortunately, computer-based technology greatly extends what is possible in terms of collecting, recording, and storing data. In addition, the advances and ready access to such technology enables the systematic analysis of large bodies of data, with many variables operating at several levels that relate to substantial numbers of cases drawn from many countries of the world. Comparisons can now be made and rigorously

examined and analyzed with respect to their maximum likelihood and the results obtained in terms of probabilities using advanced statistical and stochastic procedures (Muthén and Muthén, 2012). While comparative education now has the possibility of undertaking investigations in highly complex situations in a field in which the operations and processes of interest are taking place, it currently lacks relevant theories that can be examined through cross-national empirical studies. This article in the sections that follow addresses this issue and discusses the contributions made over the past 50 years by the IEA.

Global Education

The global education movement is a very recent development in the rapid growth of education at all levels. Little has been written about it except at the level of higher education by Maringe (2010, pp. 17–34) who conducted a World Survey to identify thematical perspectives. It is argued in this present article that the global education movement has been proclaimed and supported by the United Nations Organization since it was established in 1945. This Organization and its agencies, particularly UNESCO, have established, since 1990, the major advancement of education in countries across the world. This development was made more effective by the removal of the barriers that separated the east from the west in Europe. This coincided with a World Conference on Education for All in Thailand, which initiated a program toward 'education for all' in those countries and states that formed the membership of UNESCO. Moreover, while the implementation of the program was allocated to the regional centers of UNESCO and the UNESCO Institutes, provision was made for the subsequent following up of the implementation of the program at a World Education Forum that was held a decade later, and on similar occasions that followed in later years. This program sees education not only from a systemic perspective across its component levels, but also from a perspective that involves all countries of the world. This is a major development in education across the world. Nevertheless, while Maringe's study is of considerable value, a global theory of education has, not as yet, been advanced. There appear to be three levels within a technological perspective into which countries can be placed, namely, the developed, the transitional, and the developing countries that are identified largely with respect to their levels of technological advancement. A second perspective is argued to involve political systems with respect to the operation of democracy and democratic governance. Giddens (1999, p. 70) noted that

> Since the mid-1970s, the number of democratic governments in the world has more than doubled. Democracy has spread to over 30 or more countries, while all existing democratic states have kept democratic institutions in place.

Nevertheless, the practice of democracy in the different parts of the world varies considerably.

A third theoretical perspective of globalization is the emergence of a world culture that has arisen from the rapid and widespread expansion of the use of ICT. This also appears to be linked to the growing use of English as a global language. The issue yet to be addressed is whether a world culture can be appropriately related in a meaningful way to the continued use of native languages and the rich variety of native cultures that currently exist.

A fourth perspective involves world economic integration with the gradual freeing of trade across countries and regions of the world. A controversial aspect of this perspective involves the free movement of people across borders, and thus to form a united body of people who occupy a world in which the population is continuing to grow rapidly. The issues of world peace and sustainable development can ultimately only be resolved through the spread of education across the world, particularly in the transitional and developing countries of Asia, Africa, and Latin America.

A reaction to the expansion of global mobility and development occurred, and Beck (1999) examined the processes of individualization and commodification of everyday life in the context of the 'risk society.' Subsequently, Kell and Vogl (2012, p. 181) have considered the need for "a shift in attitude to one where there is a global optimism that overcomes some of the ambivalence and anxieties about international alliances" in order to counter the consequences of the risk society. New associations or 'ensembles' involving global education are needed that are built around cooperation, reciprocity, and concord rather than merely commercial transactions. The IEA from its formative years has been just such a body in the field of comparative education research (*see* Cross-Cultural Study of Education).

The Global Monitoring of Educational Outcomes

UNESCO in the EFA program not only undertook an interim examination of the outcomes in 2000, but also initiated from the IIEP in Paris, the establishment in Sub-Saharan Africa of the Southern and Eastern Consortium for Monitoring Educational Quality (SACMEQ) in order to collect information at regular intervals in 16 countries on the effectiveness of the EFA program. Likewise, the World Bank, a partner in the EFA program, supported similar studies in countries such as Vietnam. In addition, Postlethwaite (2004) reported, in *Monitoring Educational Achievement* published by IIEP, on studies carried out by IEA in 71 countries of the World and by the Programme for International Student Achievement (PISA) set up by the OECD, in 62 countries in Europe and in other parts of the World, with some countries being involved in both IEA and PISA monitoring studies (*see* Cross-National Comparisons in Education: Findings from PISA). Furthermore, UNESCO commissioned for the EFA Global Monitoring Report in 2008 a study on *The Growth of National Learning Assessments in the World, 1995–2006* by Benavot and Tanner (2007) from IBE in Geneva. Subsequently, Kamens and McNeely (2009) discussed the relationships between *Globalization and the Growth of International Testing and National Assessment*. They drew attention to the programs funded by UNESCO in Latin American countries through the Latin

American Laboratory for the Evaluation of Quality in Education involving 15 countries and in African and the Caribbean Francophone countries through the *Conference des Ministères de l'Éducation des Pays Ayant le Français en Parlage* with 24 participating members. IEA laid the foundations for this worldwide movement and trained the leaders of the SACMEQ and PISA programs. Similar monitoring efforts have been undertaken through the Association of the Southeast Asian Nations and the Arab League (Kamens and McNeely, 2009, pp. 7, 10).

However, at a meeting in 1958 at the UIE in Hamburg, Germany, that led to the founding of IEA, the group of scholars included Georg Rasch who argued for the measurement of performance on scales that permitted absolute comparisons to be made over time, rather than relative comparisons between countries through cross-sectional surveys (Postlethwaite, 2009, p. 4). In this way, the absolute growth in educational achievement could be measured over time that resulted from the EFA program and other similar activities. This would add to the information already made available by the UNDP through the human development index and the gender-related development index.

Systemic Research and Modeling

The global education movement, which examines the high degree of complexity of the data available, demands a new approach. The data need to be considered not just with respect to their component parts, but as a whole. Traditionally, statistical analysis, as is implied in the name of the strategy employed, involves analytical thinking. However, such an approach is inadequate where a global view is required. Under these circumstances, it is necessary to employ a holistic or systemic approach to the examination of data, in which the interrelations between the components are estimated, following the identification and hypothesizing of causal effects. This involves the advancement of structural equation models that serve to explain the situation under investigation. Such models in comparative education are necessarily both multivariate and multilevel in nature, and within them, not only direct but also indirect effects operate, which indicate the mediation and moderation of relationships. Through the use of the hierarchical linear modeling computer program (Raudenbush et al., 2011), direct effects and moderating effects across levels can be examined and estimated. Using the Mplus computer program (Muthén and Muthén, 2012), not only can direct, as well as cross-level interaction or moderated effects be examined, but indirect effects that involve mediated relationships can also be hypothesized and the magnitudes of such relationships estimated and examined for significance. In addition, Mplus can take measurement error as well as latent variables into consideration.

A further aspect of systemic research involves the hypothesizing of relationships using data aggregated to the country level that come from different sources. Between country analyses of aggregated data have been examined by Hanushek and Woessmann (2011) who have reported strong relationships that not only have statistical significance, but also have highly practical significance for the making of national policy (*see* Education, Economics of).

The Research Program of IEA

In the late 1950s, a group of scholars who met at the UIE in Hamburg saw the need for comparative studies of the relationships and processes operating to influence the educational outcomes of students' achievement and attitudes. They recognized that there was generally insufficient variability within a particular country to detect the effects of specific factors on the outcomes of learning, using the existing procedures of statistical analysis. They then argued that if research studies could be undertaken between countries, as well as within countries, then the greater variability that existed across countries and the different school systems within countries would permit the identification of common factors of importance that influenced learning outcomes.

The feasibility of conducting research studies across countries into factors influencing educational achievement was tested in a pilot study in 1960. The success of this study led to the establishment of the IEA. Over a period of 50 years, IEA has carried out a sustained program of research studies, which have, in the main, been survey and cross-national investigations, into factors that have an effect on educational achievement, participation and attainment rates, and attitudes as well as views of school and school learning. The data collected have been examined using procedures of statistical analysis across countries, between schools within countries, and between students within countries, and where possible relationships have been tested after controlling for other factors that also affected the educational outcomes under consideration.

Key Findings of IEA Research Studies

Over the 50 years during which IEA studies have been in operation, when taken together, these studies have involved millions of students in testing programs, hundreds of thousands of schools and many thousands of research workers in many different fields of educational research from a very wide range of countries. Decisions regarding which studies to conduct are made by the IEA's General Assembly, which consists of member organizations from approximately 70 education systems. The financial support for IEA's program of research has varied greatly over the years, although a very strong source of financial support has been from agencies and foundations in the United States. The school subjects involved in IEA's testing programs have included mathematics, the sciences, civic education, reading and literacy, literature and writing, French and English as foreign languages, computing, as well as ICT. In addition, studies have been conducted in preprimary and primary schools as well as in secondary schools at all grade levels, covering 13-, 14-, 15-, and 16-year-old students and at the terminal secondary school stage. Furthermore, there has been a study of classroom environments, a study to investigate the teaching and learning processes involved in mathematics and science classrooms by way of video recording of classroom operations, as well as a teacher education study to examine the pedagogical knowledge and educational experiences of trainee teachers. It is difficult to identify and highlight the 'key findings' from so many studies

in so many different areas but 10 findings stand out, although some of the 10 may be considered controversial. Six of the key findings relate to the field of comparative education, and four of these key findings relate to policy issues.

Key Findings Relating to Comparative Education

1. There are marked differences in average levels of achievement between the students in school in the more developed countries and those in the developing (LDC) countries. This occurs in spite of the fact that in the LDCs less than 100% of the relevant age groups are enrolled in school.
2. The average level of achievement within a developed country at the terminal secondary school stage is inversely related to the proportion of the age group enrolled at school or participating in the study of the subject under survey.
3. In developed countries, at the terminal secondary school stage, when equal proportions of the age groups are compared, there are only small differences in levels of achievement, irrespective of the proportions of the age groups enrolled at school. Thus, the best students do not suffer through increasing retention rates.
4. Student achievement in mathematics, French as a foreign language, and the sciences, is positively related to the time given to the study of the subject at school (1) in comparisons across countries (comparative oriented), and (2) in comparisons between students within countries (policy oriented).
5. The level of reading resources in the home is positively related to student achievement, as are other indicators of language usage in the home, such as use of (1) dictionary and (2) whether or not the language of the home is the language of instruction.
6. Measures of socioeconomic status of the home are positively related to student achievement in all countries, at all age levels, and for all subjects.

Key Findings Relating to Policy Making

7. The achievement of students is related to the time spent on homework, after other factors influencing achievement are taken into account.
8. The average level of student achievement across countries is positively related to the opportunity that students have to learn the content and cognitive skills tested.
9. In developing countries, the availability and use of text books are found to have a significant effect on student learning, but the same effects have not been recorded from studies in the more developed countries.
10. Gender differences in achievement and attitudes vary in size and direction across countries, school subjects, and over time. These differences are argued to be societally and policy based.

For further information, the *World of School Learning* (Keeves, 1995) and research reports of individual studies can be consulted (e.g., Kozma, 2003; Martin et al., 2008; Montie et al., 2007; Mullis et al., 2007, 2008).

The Three Phases of the IEA Research Programs

The IEA programs of research evolved through successive stages that were related to the duration of each study. In addition, the specific research studies have been greatly influenced by the financial support obtained and by the availability of research centers that were willing to coordinate a study. While there were several stages in the program of research studies conducted by IEA, there would appear to be three distinct phases that have operated over a 50-year period. These phases have been formed by the nature, design, and purposes of the studies undertaken.

Phase 1 Analytical Research, 1960–75

The first phase may be considered to involve primarily comparative research, with an emphasis on cross-country comparisons in the initial pilot study, which tested in 1960. The First International Mathematics Study (referred to as FIMS) commenced in 1961, tested in schools in 1964, and released an international report in 1967 (Husén, 1967). In 1966, the Six-Subject Study was initiated. Testing occurred in 1970 and 1971 and the study was completed in 1975. In 1967, a conference was held at Lake Mohonk in the United States to discuss the findings of FIMS, and in 1973, a conference was held at Harvard University to discuss the implications of the findings of the first three subject areas in the Six-Subject Study.

The Lake Mohonk conference endorsed the comparative emphasis on inquiry and cross-national comparisons using analytical statistical procedures in the examination of the data collected. As a consequence, the Six-Subject Study, for which testing occurred in 1970–71, largely followed the strategy employed in the two earlier studies (Super, 1967).

Phase 2 Descriptive and Policy Research, 1975–92

From the Harvard Conference in 1973, a change in emphasis in IEA studies toward the making of educational policy emerged in the report *Educational Policy and International Assessment* (Purves and Levine, 1975). This resulted in the undertaking of studies in the areas of mathematics, for which testing occurred in 1982 (Robitaille and Garden, 1989); science, which tested in 1984, 14 years after the First IEA Science Study (Keeves, 1992), and reading, which was undertaken in 1990–91, 20 years after the first reading study (Elley, 1994). In addition, a study of the classroom environment was carried out with data collected from 1981 through to 1983 (Anderson et al., 1989).

Furthermore, a component of the Second International Mathematics Study involved a time series or longitudinal strategy in which the same sample of students was tested on two occasions in eight countries (Burstein, 1993). A similar study had been previously undertaken in Australia that was linked to the First IEA Science Study with students tested at the 13-year-old level (Keeves, 1972). Nevertheless, in the later reports and analyses of the science and reading studies, work was done on the examination of changes in levels of achievement at the system level over time, referred to as

a trend or a type of longitudinal strategy (Keeves, 1992; Lietz, 1996). These two studies used Rasch scaling procedures to examine absolute change at the system level over time.

Phase 3 Monitoring and Evaluation Research, 1992 and Ongoing

In the third phase, the direction of the major studies that were very strongly supported financially by the United States placed an emphasis on trends over time through the preparation and publication of so-called league tables. The statistical procedures employed were directed toward the very efficient estimation of national mean scores, with small estimates of error, so that the statistical significance of relative change of differences between countries could be made as part of an evaluation process. Little attempt would appear to have been directed toward monitoring and the examination of absolute change in performance between countries or on the absolute change in performance between grade levels within countries. However, this work resulted in a series of Trends in Mathematics and Science Studies (TIMSS) with testing taking place at intervals of 4 years. Likewise, a series of studies has been carried out at 5-year intervals arising from the study of reading literacy undertaken in 1990–91 (Elley, 1994) that are referred to as the Progress in International Reading Literacy Studies (PIRLS). Data collections for TIMSS and PIRLS coincided in 2011 with the international reports and databases that were released at the end of 2012 (Martin et al., 2012; Mullis et al., 2012a,b).

As an extension of TIMSS, IEA designed and implemented a video study of instruction in the mid-1990s with seven countries participating in the mathematics part and five countries participating in the science part (Jacobs et al., 2003; Stigler and Hiebert, 1999). National samples of mathematics and science lessons were videotaped in an attempt to obtain better information about teaching practices in these subject areas. These studies were highly innovative at that time.

In addition to TIMSS and PIRLS, IEA comparative research studies in other areas of education continued to be coordinated in other centers that were led by scholars in research institutes and universities who maintained a strong interest in comparative and analytical investigations into new fields that were emerging as a result of advances in technology and the drive toward democratic government that accompanied the globalization movement.

These IEA studies included (1) the International Civic and Citizenship Study in 2009, which incorporated novel regional assessment modules for Asia, Europe, and Latin America (Kerr et al., 2010; Schulz et al., 2010, 2011) and built upon the earlier Civic Education Study (Torney et al., 1976); (2) the Teacher Education Development Study conducted in 2008, which was IEA's first study of tertiary education, with a focus on policies and practices in mathematics teacher education (Tatto et al., 2008); and (3) International Computer Information Literacy Survey with a planned data collection in 2013, which builds on a tradition of IEA surveys carried out between 1989 and 2006 on ICT use in schools, but features a new computer-based student assessment of computer and information literacy.

Systemic Research and the Use of Models

In research studies that are primarily concerned with the making of decisions to guide policy and practice, specific hypotheses are advanced and tested. In a modeling approach to research, a model set within a system of operations is advanced and examined in the context in which the study is conducted. Initially, IEA's program of research was undertaken largely from the perspective of comparative education that was enriched by ideas drawn from psychology, economics, demography, sociology, and pedagogy. Before the systemic examination of educational processes, practices, and policies between students, between schools, and between countries can take place, progress must be made along three lines. First, it is necessary for theory to be advanced and models formulated or constructed of the specific processes involved in school learning. Second, it is necessary for data to be collected that are sufficiently comparable across countries, so that the examination of models in a comparative manner is meaningful. Third, statistical procedures for the examination of models must be developed in order to provide strong estimates of effects and the efficient estimates of errors for the examination of statistical significance and effect sizes.

Several models have been widely employed in comparative research studies both within and between countries in the 30 or more IEA studies carried out. From an IEA training workshop conducted at Gränna in Sweden in 1971, a model of curriculum implementation that operated at three levels was advanced. In this model shown in **Figure 2**, the curriculum can be considered to exist at three levels: (1) the intended curriculum, (2) the implemented curriculum, and (3) the achieved curriculum, which are influenced by antecedent and contextual factors as well as the learning conditions and the teaching practices operating in the schools. A second model of school learning was advanced by Carroll (1963) that has been the source of many theoretical discussions of the factors influencing educational achievement. The IEA studies provided opportunities for such discussions and for the derived models to be examined with empirical data (Carroll, 1975). Three variables were specified in the model of school learning in terms of time: (1) aptitude, which involved the amount of time a student would require to learn a task to a specified criterion level, given motivation, opportunity to learn, and optimal quality of instruction, (2) perseverance, which involved the amount of time that a student was willing to engage in active learning, and (3) opportunity to learn, which involved the amount of time provided for learning in a specific program. In addition, two variables were advocated that were not specified in terms of time, namely, (4) the ability to understand instruction, and (5) the quality of instruction provided.

A third model that has guided IEA's research has been a cross-national model of educational achievement in a national economy that was advanced by Dahllöf (1967). This model covered the (1) national economy, (2) demand for human resources, (3) objectives, (4) structural and frame factors, (5) process factors, and (6) levels of performance achieved and attainment. Walker (1967) advanced a fourth model for the effects of selection. In this model, each complete age group in a country had a similar distribution of ability and largely common curricula and common modes of

Figure 2 The context and components of the school curriculum. Source: Rosier, M.J. Keeves, J.P. (eds.), 1991. The IEA Study of Science I: Science Education and Curricula in Twenty-Three Countries. Pergamon Press, Oxford, p. 7, modified.

instruction were assumed to exist across countries. Differences in selection, retention, and participation influenced the level and spread of achievement test scores across countries as well as the yield of a school system.

In general, such models were examined with available data across the countries participating in the IEA studies. However, they were sufficiently complex that their examination was restricted by the statistical procedures available at the time. For example, in the model depicted in Figure 2, the model was examined at the student level, or at the school level or at the country level, but it could not be examined across all three levels simultaneously. However, it is now possible to examine such a model, in a single analysis across all three levels, with students nested within schools and schools nested within countries, so that the systemic structure of the model can be taken into consideration.

The IEA studies, both in sampling design and statistical analyses were initially strongly guided by Gilbert Peaker. He, having worked at Cambridge University in England, was greatly influenced by Sir Ronald Fisher, who advanced and developed the Fisherian tradition of statistical analysis. Although IEA sought assistance and advice from scholars working within a decision-making perspective in the Neyman – Pearson tradition and the Bayesian perspective, which took into consideration prior knowledge, Peaker's influence dominated the statistical analyses of the large bodies of IEA data. He adopted a stochastic view for the investigation and estimation of effects relating to educational policy and practice and the introduction of structural equation modeling into IEA studies during the first 30 years from 1960 to 1990. Only in the twenty-first century has the examination of hierarchical linear models and structural equation models started to be more widely used in the analyses of IEA data. Initially, partial least squares regression was advanced by Herman Wold, from Sweden, alongside the use of maximum likelihood procedures developed by Lawley from Scotland and by Jöreskog also from Sweden, where the IEA Headquarters were located, for the examination of models of educational processes. Still, while the estimation of the coefficients of structural models is relatively straightforward, the meaning and interpretation of these effects in both simple and complex models are more somewhat complicated as discussed by Pearl (2000) and more recently by Hoyle (2012).

Regression analysis was employed for the comparison of groups both within countries and between countries. While not feasible in the early IEA studies due to limitations in terms of modeling and computational power, more recent IEA studies have paid appropriate attention to examining the extent to which measures of both cognitive skills and contextual background constructs are comparable between countries and between subgroups within countries, as defined by, for example, gender, remoteness, or migration status. For cognitive skills test items, this tends to involve the examination of differential item functioning between countries and between male and female students. Such analyses were first undertaken for the IEA Reading Literacy Study in 1990/91 (Elley, 1994) and are continued to be applied in IEA's TIMSS and PIRLS assessment programs (see, for example, Foy et al., 2012). For background questionnaire constructs such as students' interest in the subject matter or school climate, this involves the examination of results from separate multigroup confirmatory factor analyses models where the groups can be defined, for example, by country or gender. Such analyses examine the extent to which the measurement model fits the data overall and in each particular subgroup. Four levels of measurement invariance are usually assessed, namely, configural, metric, scalar, and uniqueness invariance (see Meredith, 1993; Vandenberg and Lance, 2000). Each level of invariance increases in the restrictiveness of its assumptions from configural invariance – which holds if the same number of factors is found and the same items are associated with each factor across groups – to uniqueness invariance, which restricts the portion of item variance not attributable to variance in the underlying factor to be the same across groups.

However, it should be recognized that with data from large samples, which is the case in IEA studies, even smaller differences appear to be significant and that, therefore, using significance test to judge the level of invariance may tend to be problematic. Consequently, rather than examining the absolute

significance of the goodness-of-fit indices, relative changes in model fit across different multiple-group models with different equality constraints on parameters are reviewed (Schulz, 2009). More recently, however, Davidov et al. (2012) have shown how multilevel structural equation modeling can be applied to explain why invariance at the higher levels might be absent in large-scale cross-national research. In IEA studies, such invariance analyses have been applied, for instance, in the Civic and Citizenship Study (see Schulz and Friedman, 2011).

Comparative Research in Education in the Future

Very little work has been done by scholars in the field of comparative education to advance models for examination and the estimation of significant relationships and causal effects using the statistical programs that have been written during recent decades. However, Fägerlind and Saha (1989) advanced ideas and relationships toward the construction of a typology for education and development that was dialectical in nature with economic, political, and social, including cultural and ideological, dimensions. This model was then examined with respect to the Indonesian educational system, from a comparative perspective but without data being available for statistical analyses.

The report of the Lake Mohonk conference in 1967 considered the theoretical foundations that were seen to be required for the next stage in the IEA research program. The variability between countries in their economic circumstances was seen to be related to the differences in the provision of education in each country and to the nature and levels of achievement attained at successive levels of schooling. The comprehensive model of educational achievement advanced from the conference is presented in Figure 3 (Super, 1967).

Figure 3 was developed prior to an awareness among educational researchers of the possibilities of employing path analysis and using least squares regression procedures. The model sought to include the stages of input, process, output, and utilization in a multilevel framework with appropriate variables linked together by the flow of paths of influence. This model has given rise as well as the need to develop stochastic procedures for the analyses of large bodies of data and the estimation of models with many structural relationships. The development of Mplus (Muthén and Muthén, 2012) for the analyses of multivariate and multilevel structural equation models to investigate cross-level and within-level moderated effects together with mediated effects operating at three levels now enables the examination of complex models derived from Figure 3. Thus, this model and the model depicted in Figure 2 have guided, either explicitly or implicitly, the analyses of many IEA studies and have thus contributed extensively to the advancement of the body of knowledge in comparative education.

It is evident that the establishment of IEA has already given rise to a very substantial body of research, since over the past

Figure 3 A comprehensive model of educational achievement. Source: Super, D. E. (Ed.), 1967. Towards a Cross-National Model of Educational Achievement in a National Economy. Teachers College, Columbia University, New York, p. xx (12) modified in Postlethwaite, T.N., 2009. Memories of IEA achievement surveys. In: Matthews, B., Gibbons, J.A. (Eds.), The Process of Research in Education. Shannon Research Press, Adelaide, pp. 1–20.

50 years IEA has conducted 31 major studies (Schwille, 2011, pp. 657–658). The fascinating story of the endeavors of thousands of people who have participated in IEA's journey in the area of comparative research has recently been documented (Papanastasiou et al., 2011). Nevertheless, there is clearly a need for rethinking the nature of research in comparative education in an international and global education context from new theoretical perspectives to serve researchers in the educational, behavioral, and social sciences as well as educators, policymakers, and teachers at all levels in the decades ahead.

Conclusion

While the Lake Mohonk model presented in **Figure 3**, together with the comparative, policy-oriented, and monitoring approaches, has guided either explicitly or implicitly the analyses of many IEA studies and thus contributed extensively to the advancement of the body of knowledge in comparative education, the advent of globalization requires a new approach.

Hanushek and Woessmann (2011, p. 192) have argued that with

> …sets of comparable achievement data for extensive samples of countries being linked to subsequent economic growth, and with the emerging long panels of regular achievement data for large samples of countries, the outlook for future research in the economics of international differences in educational achievement is clearly bright.

An interesting example that illustrates how use can be made of such data by employing procedures suggested by Hanushek and Woessmann can be found in the recent McKinsey Report (Mourshed et al., 2011), which examines how 20 school systems are able to sustain their rising levels of school achievement.

Finally, if information can be collected from other disciplinary perspectives in order to extend beyond the field of economics, and with the appropriate statistical procedures now available, the future of comparative educational research is moving into rich and fertile fields. These fields, as Hanushek and Woessmann have argued, are formed from the large monitoring studies that are currently in operation across the world. In addition, the systemic research studies that are envisaged and illustrated by the work that Hanushek, Woessmann, and their colleagues are already undertaking are comparative and systemic in nature, and not solely directed toward the making of policy or the evaluation and monitoring of existing programs of educational development in a global setting (*see* Education, Economics of).

Comparative Studies: Method and Design

Abstract

Mill's canons are the comparative procedures described by John Stuart Mill in his famous work *A System of Logic* (1843). Among these procedures, in particular, are the following: (1) *the method of agreement*, comparison of two or more cases identifying their commonalities, ideally a single one as the common cause of a phenomenon; (2) *the method of difference*, comparison of two or more cases identifying their differences, ideally a single one (thus controlling for all others), as the cause of a phenomenon; (3) *the indirect method of difference*, double employment of the method of agreement once before and once after a certain event to identify an external effect (stimulus) that may have occurred in the meantime as in a 'quasi-experiment'; and (4) *the method of concomitant variation*, identification of factors that vary with others in a regular manner. Internal validity is the (approximate) causal relationship of two or more variables with each other. External validity is the generalization of a presumed relationship across other cases, settings, and time. Small *n* is the characteristic research situation for the 'comparative method' in the narrow sense of the term, ranging from single-case analysis ('configurative') to large *N* analysis in which statistical procedures, ideally based on random sampling from large entities, can be employed. Most similar systems–different outcomes is a systematic matching procedure to identify distinguishing factors between cases possibly responsible for the divergent outcome, while controlling for all others. Most different systems–same outcome is a systematic contrasting procedure to identify possible common factors for the same outcome, while eliminating all others. Multiple causation is the (necessary) combination of several variables to have a certain effect. Conjunctural causation is different combinations of variables having the same effect. Qualitative comparative analysis is a recent comparative technique used to analyze varying complex configurations of variables reducing them to their minimal expressions with the help of Boolean algebra.

Definition

Comparisons are essential in any science to establish systematic similarities and differences between observed phenomena and, possibly, to develop and test hypotheses and theories about their causal relationships. Whereas this broad definition of comparative inquiry includes several distinct methods, including case studies, statistical analysis, and experimental research, the comparative method in the narrower sense of the term characteristically involves a limited number of cases (small *n*) but usually complex phenomena and relationships often at the macro level of entire societies or political systems. In this latter sense, this article discusses comparative studies' method and respective designs.

Intellectual Context

Comparative procedures in the historical and political sciences date to antiquity, but their methodological backgrounds have been developed systematically in the natural sciences in the eighteenth and nineteenth centuries based on studies, for example, by Linné in botany, Cuvier in anatomy, or Bernard in experimental medicine. The logical foundations for this method were laid by Hume and, in particular, J. S. Mill's (1843) canons. The first of these refers to the method of agreement eliminating all similarities but one: "If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon" (p. 390). By contrast, the method of difference establishes the absence of a common cause or effect, even if all other circumstances are identical: "If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring only in the former; the circumstance in which alone the two instances differ, is the effect, or the cause, or an indispensable part of the cause, of the phenomenon" (p. 391).

Thus, both methods are concerned with the systematic matching and contrasting of cases to establish common causal relationships by eliminating all other possibilities. Both procedures are, however, somewhat extreme in the sense that they attempt to establish a single common cause, or its absence, by controlling all other possibilities and the entire environment. The method of difference, to some extent, can be approximated in pure laboratory situations in which such experiments may be conducted. The method of agreement is more applicable in field research situations, but then the question of how to control the environment becomes crucial (*see* Field Observational Research in Anthropology and Sociology).

Mill, therefore, devised a combination of the two methods, which he called the joint method of agreement and difference or the indirect method of difference, which consists of a double employment of the method of agreement, once before and once after a certain event: "If two or more instances in which the phenomenon occurs have only one circumstance in common, while two or more instances in which it does not occur have nothing in common save the absence of that circumstance, the circumstance in which alone the two sets of instances differ, is the effect, or the cause, or an indispensable part of the cause, of the phenomenon" (Mill, 1974: p. 396). This quasi-experimental design, however, as Mill himself realized, is less cogent than the pure method of difference.

A fourth method, which is a derivation of the method of difference, is the method of residues. When cause and effect of other factors have been established by previous experiments, remaining variation in the outcome can be attributed to the residues in the original experiments: "Subduct from any phenomenon such part as is known by previous inductions to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents" (Mill, 1974: p. 398).

Finally, for instances in which a certain common external factor cannot be entirely eliminated by any of these procedures, its impact at least may be systematically varied from one situation to another (e.g., altitude above sea level, or heat or air pressure in certain experiments in physics) and then its varying influence assessed. This is the method of concomitant variation: "Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation" (Mill, 1974: p. 401).

Changes in Emphasis

Mill's canons imply rather rigid 'positivist' assumptions about the relationships of cause and effect and the state of valid theory in any given area of research. These are (1) contiguity between the presumed cause and effect; (2) temporal precedence, in that the cause had to precede the effect in time; and (3) constant conjunction, in that the cause had to be present whenever the effect was obtained (cf. Cook and Campbell, 1979: p. 10). On the whole, such relatively mechanical and deterministic relationships can be established only rarely even in the hard sciences.

By themselves, therefore, these methods do not produce any new *discoveries* unless some truly relevant factors have been included. Similarly, they may not *prove* any causal relationship unless a clear and complete (preconceived) model of such links has been tested and other factors have been controlled sufficiently. Even such a model eventually may be falsified and be integrated in a more comprehensive theory. So these methods may not produce any positive results. They constitute, however, a valuable step to eliminate many irrelevant factors and to approximate the causal conditions in the real world. In this sense they correspond to Popper's (1934) famous principle of falsification. Or as it was expressed in another classic of this period, Mill's methods are nevertheless "of undoubted value in the process of attaining truth. For in eliminating false hypotheses they narrow the field in which true ones may be found. And even where these methods may fail to eliminate all irrelevant circumstances, they enable us with some degree of approximation to so establish the conditions for the occurrence of a phenomenon, that we can say one hypothesis is logically preferable to its rivals" (Cohen and Nagel, 1934: p. 267).

If these qualifications have to be made from a general epistemological point of view, they apply even more to the social and behavioral sciences where objective facts and their subjective perceptions are closely interlinked and may change in the course of time. Mill himself was aware of the much higher complexity in the social sciences and the inapplicability of his methods in a strict sense: in "politics and history … Plurality of Causes exists in almost boundless excess, and effects are, for the most part, inextricably interwoven with one another. To add to the embarrassment, most of the inquiries in political science relate to the production of effects of a most comprehensive description, such as the public wealth, public security, public morality, and the like; results liable to be affected directly or indirectly either in *plus* or in *minus* by nearly every fact which exists, or event which occurs, in human society" (Mill, 1974: p. 452, emphases in the original). He, therefore, found the method of difference inapplicable and the methods of agreement and concomitant variation inconclusive in the social sciences (p. 881 ff.). Similarly, the method of residues requires a much more developed state of theory than is usually available in the social sciences (p. 884 ff.).

In the realm of the human and social sciences, however, Mill was willing to adopt a less deterministic and more probabilistic perspective:

> Inasmuch as many of those effects which it is of most importance to render amenable to human foresight and control are determined, like the tides, in an incomparably greater degree by general causes, than by all partial causes taken together; depending in the main on those circumstances and qualities which are common to all mankind, or at least to large bodies of them, and only in a small degree on the idiosyncrasies of organization or the peculiar History of individuals; it is evidently possible with regard to all such effects, to make predictions which will almost always be verified, and general propositions which are almost true. And whenever it is sufficient to know how the great majority of the human race, or of some nation or class of persons, will think, feel, and act, these propositions are equivalent to universal ones. For the purpose of political and social science this is sufficient (Mill, 1974: p. 847, emphases in the original).

Emphases in Current Theory and Research

Two basic problems remain in any research of this kind, namely, the questions as to what have been called the 'internal' and 'external' validity of any scientific findings (*see* Internal Validity; Causal Counterfactuals in Social Science Research). The first refers to the "approximate validity with which we infer a relationship between two variables is causal," the second refers to the "approximate validity with which we can infer that the presumed causal relationship can be generalized to and across alternate measures of the cause and effect as well as across different types of persons, settings and times" (Cook and Campbell, 1979: p. 37). Even though both kinds of validity can only be approximated and remain subject to the possibility of further falsification, they can be established with some kind of certainty with the help of procedures of randomization.

Regarding internal validity, Mill's original procedures can be enhanced by first randomly selecting two groups of subjects and then administering a certain stimulus or treatment to one of them. If a significant effect can be observed in the selected group, then the stimulus may be considered to have been the cause. This corresponds to Mill's method of difference, but where all kinds of external influences can now be controlled, within certain limits, by the equalizing procedure of random selection. This is the realm of experimental research proper.

Similarly, if a random sample has been drawn from a larger universe of persons, as for example in survey research, the relationships that can be observed in the sample may be generalized to the larger universe from which it was drawn. This is the realm of statistical analysis (*see* External Validity).

Unfortunately, however, both procedures of randomization are not feasible when we deal with the characteristic many variables–small *n* situation of many kinds of current social research at the macro level apart from the fact that many real experiments with groups of human beings are not possible for practical, political, or ethical reasons either. We are thus left with Mill's original predicaments and have to attempt to cope with them in some other ways. This depends, of course, on the kinds of cases and problems we are dealing with and the state of theory in any given area of investigation. In social research, cases often refer to larger distinct groups of people, for example, certain ethnic groups or entire societies and states that have a proper name and in which we are interested because of their intrinsic relevance and not just as an anonymously selected unit out of a multitude of cases.

The kinds of problems we are dealing with vary according to the respective emphasis of the different social and behavioral sciences. What they have in common is the multidimensionality (i.e., including objective, subjective, and often also normative dimensions) and the malleability (i.e., possible changes over time and probabilistic internal relationships) of their subject matter (Almond and Genco, 1977). The ways such relationships are perceived depend on the social (i.e., also theoretical) constructions of this reality. These, by necessity, can only be certain approximations as to their real (and changing) nature, but they have concrete referents and are not, in our view, entirely arbitrary whims of imagination as some of the more extreme postmodern authors pretend (*see* Postmodernism: Methodology). What to compare thus differs from one discipline to the other and depends on the respective state of theory.

By contrast, here we are concerned with *how* to compare under particularly difficult conditions problems of internal and external validity in the social sciences. From this perspective, a number of ways can be conceived to cope with the prevailing small *n*–complex cases dilemma. First, the number of cases may be increased, including for example, historical cases or investigating them at some lower level of analysis (e.g., certain districts or provinces rather than entire nation-states). But even then, neither randomly selected control groups nor random sampling for statistical purposes are possible. In any case, we usually are interested in concrete societies and their problems and not in any anonymous units of investigation. A second strategy concerns the purposeful selection of cases, and a third strategy concerns the reduction of complexity by means of combining several variables or employing better theory.

At the outset of any investigation, an area of homogeneity must be defined that establishes boundaries for the selection of cases. Cases must parallel each other sufficiently and be comparable along certain specified dimensions. This is meant by the common saying that apples and oranges should not be compared. In this regard, the subject matter and the problem in which we are interested must first be specified to make any sense. Thus, these fruits may well be compared concerning their sugar or water contents, their nutritional value, and so on when these dimensions as the *tertium comparationis* have been made explicit. The specification of relevant cases at the start of an investigation thus amounts to an explicit or implicit hypothesis that the cases selected are in fact alike enough to permit comparisons. The primary consideration in delimiting cases for a small *n* comparative study is the dependent variable. For example, the breakdown or survival of democratic regimes in interwar Europe presupposes the prior existence of some form of democracy in the selected cases. In addition, some limitations in time and space can enhance the homogeneity and thus the comparability of the cases examined. For example, certain kinds of colonial or other forms of external domination or religious-cultural influences may be useful criteria for selecting a specific group of cases. Area studies, for example, are based on such assumptions of regional, historical, or cultural homogeneity.

A second consideration concerns the extent of diversity within the selected universe. In this regard, a maximum of heterogeneity for a minimum number of cases should be achieved. Taking the previous example again, both survivors and breakdowns of democracy can be considered, and among the latter perhaps some more specific variants such as fascist versus more generally authoritarian outcomes.

Within this universe, two opposite strategies now become possible. One is the most similar system and the other is the most different system design. These have been explicitly formulated and discussed by Przeworski and Teune: "The most similar systems design is based on a belief that a number of theoretically significant differences will be found among similar systems and that these differences can be used in explanation" (1970: p. 39). By matching these similar cases as much as possible, most of the variables can be controlled. Mill's indirect method of difference, in which different outcomes may be attributed to the remaining factors that differentiate these cases, now becomes applicable. Even though only rarely just a single factor will remain to which the effect can be attributed, at least many others can be excluded, and the remaining ones can be examined more closely in a theoretically guided qualitative manner. The internal validity of the observed relationships thus can be greatly enhanced.

The opposite strategy is the most different systems design: this design, "which seeks maximal heterogeneity in the sample of systems, is based on a belief that in spite of intersystemic differentiation, the populations will differ with regard to only a limited number of variables or relationships" (Przeworski and Teune, 1970: p. 39). This contrasting of cases thus eliminates all factors across the observed range that are not linked to an identical outcome. In this way, more universal explanations are sought as far as the selected area of homogeneity is concerned. To some extent, the external validity of some hypothesized causal relationship can be extended and the range of its applicability, including certain limitations in time and space, can be established.

Until recently, however, these designs had not been fully operationalized. Several problems must be addressed that follow from the necessity of measuring the proximity or remoteness of pairs of cases in the heterogeneous, multidimensional space defined by the independent variables. These distance measures provide the basis for determining the most

different and most similar pairs or groups of cases with regard to the respective outcome. The two main issues are (1) choosing from among a variety of different ways of measuring the distance between pairs of cases in a multidimensional space; and (2) assigning relative weights to the variables that define this space. In this way, the complexity of the data can be retained as much as possible in the complexity of the proximity measure. These procedures then make it possible to identify most different systems–same outcome (MDSO) and most similar systems–different outcomes (MSDO). The causes of different outcomes may now be assumed to lie in the commonalities that remain among MDSO cases and the differences that distinguish MSDO cases (for such operationalizations see Berg-Schlosser and De Meur, 2009).

Another strategy for dealing with the many variables – few cases dilemma concerns the variables side. Here, for reasons concerning the internal validity of Mill's methods, one should take a rather comprehensive approach not to leave out any possibly relevant variables. This, of course, depends on the state of theory in any given area of investigation, but usually in the social sciences, several contending or supplementary hypotheses should be considered. Furthermore, not only bivariate relationships with an independent variable and the respective outcome but also the possibility of more complex causal problems – for example, multiple (several variables combined have a certain effect) or conjunctural ones (alternative combinations of different variables may lead to the same outcome, i.e., equifinality) – must be taken into account.

One technique is to look for constants across the observed cases. If one variable turns out to be consistently linked to a particular outcome, it becomes a strong candidate for inclusion in any explanation as a necessary but perhaps not sufficient condition. A related approach focuses on correlations between the independent variables and the dependent variable. Like the search for constants, the examination of correlations may provide strong hints. More sophisticated techniques include discriminant analysis and logistic regression (applied to dichotomous outcome variables). A relatively large number of variables can be simultaneously treated in this way. These techniques typically are used to assess the net, additive contribution of each independent variable to some outcome. Variables that are uncorrelated with other variables but strongly correlated with the outcome are favored by these methods. Thus, these techniques are biased toward causal factors that act independently, not conjuncturally.

These statistical approaches are useful to identify broad patterns, but they are of limited utility in situations of causal complexity. Most complex causal combinations are hidden from analyses based on correlations. For example, if a variable must be present in some conjunctures for an outcome but absent in others, the correlation between this cause and the outcome may be 0. Qualitative comparative analysis (QCA), a recent comparative technique based on Boolean algebra and set theory (cf. Ragin, 1987), can be used in situations of causal complexity. In contrast to the linear techniques just described, QCA focuses on configurations of variables. In QCA, an independent variable can be eliminated from an analysis if it does not uniquely distinguish any case that manifests an outcome from at least one case lacking the outcome.

Other techniques for reducing the number of variables focus on patterns among the variables. In light of relevant theoretical and empirical knowledge, investigators may select a more limited number of major variables or reconstruct them in different ways. Such reductions may proceed statistically. For example, researchers often use factor analysis to combine correlated variables into single indices.

Qualitative techniques for constructing more encompassing causal variables also are possible. For example, in the interwar study, the existence of a rural proletariat and large-scale landlords has been combined into the more encompassing concept of feudalism. Similarly, a Boolean addition of factors, constituting alternative constellations in combination with another variable, may be possible. For example, the presence of ethnic, religious, *or* regional social cleavages in the absence of any overarching (verzuiling) structures was combined to the variable of social heterogeneity in the study of democratic breakdowns and survivals (Berg-Schlosser and Mitchell, 2002). Use of ideal-typical constructs also can be conceived of as reductions of complexity emphasizing some characteristics and deemphasizing others. In this way, the overall number of variables may be reduced considerably while still retaining much of the original information. With the help of such strategies, both from the cases and the variables sides, the relationship between their respective numbers may be reduced to manageable proportions, thus avoiding the problem of overdetermination when the latter exceed the former.

QCA can be employed for other purposes. In its crisp-set version, it is based on dichotomized variables (which, however, can be constructed as dummies from multichotomous or interval ones) and reduces, by employing certain algorithms, the observed complexity of possible independent factors with regard to a particular outcome to a minimal logical formula (or several alternative ones) taking account of the possible interactions of these factors. The most important rule in QCA is as follows: "If two Boolean expressions differ in only one causal condition yet produce the same outcome, then the causal condition that distinguishes the two expressions can be considered irrelevant and can be removed to create a simpler, combined expression" (Ragin, 1987: p. 93). For example, if the combination of three factors A * B * C or A * B * c lead to the same outcome O (where upper case letters signify the presence and lower case letters the absence of a condition) then this expression can be reduced to A * B = O.

QCA can thus (1) examine a universe of cases with regard to a given output in an exhaustive manner; this description will be the most concise, including all possible alternate minimal expressions that allow for the most parsimonious interpretations; (2) test hypotheses by showing whether they are consistent with the combinations described; if many contradictions occur, the hypothesis fails; and (3) deduce the shortest possible formulas, describing the simplest subset of actual, potential, or counterfactual cases not contradicting the respective outcome; in this way, more general expressions can be deduced by using simplifying assumptions. QCA thus serves some of the most important aims of any science, namely, systematic description and the falsification and construction of theories.

QCA shares some of the problems and limitations concerning the loss of information and a certain amount of arbitrariness

in setting cutting-points for dichotomized variables. In contrast with common statistical procedures, however, it retains the full complexity of all cases and all variables considered. Nonunique formulas may emerge, but this must be considered a strength and not a weakness. It deals explicitly with outliers and covers them fully. It can arrive at several conjunctural constellations that explain the same outcome. When several different formulas cover a single case, the technique forces the researcher (as the MSDO technique) to take a closer look at the results and to *interpret* them in light of the historical knowledge of the case. In comparative inquiry, this approach is preferred to a purely mechanical procedure that, in many statistical analyses, entirely obscures the fate of particular cases. Here, in fact, begins the real *qualitative* work, depending very much on the training and quality of researchers, their in-depth knowledge of cases, as well as their sensitivity and understanding.

More recently, the possibility to include multivalue conditions (variables) for QCA has been incorporated in a new software (TOSMANA, i.e., tools for small *n* analysis) together with new features visualizing thresholds and Venn diagrams (Cronqvist and Berg-Schlosser, 2009). In this way, more information can be retained, but in a small *n* world, this procedure should be used sparingly not to individualize each case, that is, having distinct expressions for each of them and no longer broader patterns of cases.

Ragin (2008) has developed this approach further by employing fuzzy sets instead of crisp sets for a QCA analysis. This allows for the use of continuous (calibrated) scales on all conditions and includes measures of coverage (percentage of cases included) and consistency (degree of subset membership in a multidimensional vector space). It also can identify necessary and sufficient conditions in separate steps. Fuzzy set analysis, incorporating some probabilistic assumptions and parameters, requires, however, a somewhat larger (medium) *N* of 25 or so cases and above. On the whole, this approach constitutes a viable set-theoretical alternative in small and medium *N* settings to common statistical procedures and has found numerous applications across various social science fields.

Methodological Issues and Problems

Even though the small *n* comparative method and the statistical methods have distinct applications, each with its own advantages and problems, different schools of thought have formed around these approaches fraught with controversies. In part, these reflect remaining biases; to some extent, however, they are based on real problems that cannot be easily resolved. Some of these issues have been stated as quantitative versus qualitative, and case-oriented versus variable-oriented, holistic versus analytic, or deterministic versus probabilistic research. To some extent these distinctions pose false alternatives and represent differences in emphasis rather than in kind. Thus, statistical procedures are, by their very nature, based on larger quantities, but small *n* analyses similarly may deal with numbers and quantitative data. Qualitative aspects refer to the presence or the absence of a factor, as in QCA, but should not be confounded with qualitative methods as, for example, hermeneutics or participant observation (*see* Interpretive Methods: Macromethods; Participant Observation) in a different sense of the word.

In the same way, case-oriented means that emphasis is laid on a number of known and theoretically or historically particularly interesting and relevant cases, as opposed to, for example, the anonymous ones in random sampling, but all scientific inquiry is based on distinct units (cases) and variables and a number of relevant observations (King et al., 1994). *Holistic* is also a misleading term referring to the usual higher complexity of case-oriented research, but it does not mean in this context that cases can only meaningfully be understood in their entirety (e.g., in Confucian philosophy) as opposed to critical-rational analysis.

Finally, deterministic is a misnomer for procedures based on Millian methods or logical distinctions as in Boolean algebra. Only the presence or absence of a factor is referred to and not its probabilistic nature with respect to its effect on the internal or external validity of any particular finding. Logically minimized relationships found by Boolean procedures can be as spurious as correlational analysis. The revealed patterns indicate different more complex qualitative constellations, but they are not based on their relative frequency or probabilistic inferences.

As to the real problems, however, these persist and only certain approximations or trade-offs between certain emphases are possible. Millian methods and similar ones can serve only to eliminate false hypotheses and to delineate the conditions for the occurrence of a phenomenon (Cohen and Nagel, 1934). Within this realm, the truly qualitative and interpretative skills of knowledgeable experts are needed to provide meaningful assessments of the factors involved. These procedures may be more tedious and less universalistic, but they are often more meaningful and less superficial than many of the macroquantitative studies.

Most small *n* comparative studies, as well as the majority of statistical analyses, have been cross-sectional and static. There have been some advances in the statistical field in recent years as far as pooled time-series and event-history modeling are concerned (*see* Event Sequence Analysis: Methods), but these share some of the limitations and the relative superficiality of macroquantitative procedures. There are, as yet, no truly dynamic procedures incorporated in the MSDO or QCA techniques combining both cross-sectional and longitudinal aspects in a macroqualitative way. These still rely more on well-informed thick narratives (*see* Thick Description: Methodology), but some specific path-dependent techniques have been developed more recently.

A further limitation refers to the structure (macro-) and actor (micro-) dimensions of any social and, by implication, comparative analysis. Most comparative studies are concerned with the broader and presumably more enduring structures of social processes both in time and space. The final outcome, nevertheless, may very well depend on any particular (group or individual) actor in the analyzed chain of events. Again, only certain approximations can be arrived at in this regard and certain trade-offs between more universalizing, variation-finding, and individualizing approaches (Tilly, 1984) have to be made. No macro–macro shortcuts should be made in sociological explanations because concrete subjects with their respective perceptions and preferences always are involved, which only in a later step may be aggregated at a meso or macro level (Coleman,

1990). Whether these actors should be conceived of as rational do not concern us in this context. The broader structural aspects can be conceived as the opportunity set within the boundaries of which actual actors operate and respective choices are made.

A final point must again be mentioned, the problem of inference. The unified logic of inference of both quantitative and qualitative research has been emphasized once more by King et al. (1994). In spite of many important issues that are raised and clarified by the authors, their experiences and recommendations lean too strongly on the quantitative side of research. This relates both to the internal and external validity of the inferences to be drawn. In terms of the internal causal chains that should be established, King et al. look at them from the side of the independent variables in a forward sense toward their eventual effect on the outcome. Much of small *n* comparative research, however, is concerned with disentangling the different influences on an outcome from a backward perspective or through process tracing to identify the different factors in their complex interactions over time involving the major structures and actors, but also many contingent and unique aspects. This resembles more a detective's investigation of a crime or an accident than any more nomothetic generalizing scientific efforts and remains idiographic (Brady and Collier, 2010). The more complex pattern of causality that has been established in this way in terms of its internal validity can then serve to devise new more complex hypotheses that can be tested across more similar (comparable) cases and, possibly, establish a certain range of their external validity. A much stronger theory may thus emerge.

Probable Future Directions of Theory and Research

The strength of the comparative method lies, therefore, in its critical applications to theory testing and development. The state of affairs of theory building in the social sciences remains relatively weak and is subject to specific problems and restrictions and to the general malleability of its substance. Even if only certain approximations can be reached, the relevance of many macrosocial and political problems – for example, in policy research, institution-building, constitutional engineering, and so on – for potentially millions of people make it worth every effort. Better theory, in the longer run, then also may contribute to a better practice.

It is difficult to predict any more distinct developments in this regard, but at least some of the *desiderata* that reflect some of the existing deficiencies can be outlined. First of all, many more existing propositions across the various fields of social inquiry based on other methods of data collection and theory building should be subjected to systematic testing by comparative methods as far as they refer to small *n* environments. Counterfactual examples and most different cases should be sought to establish their respective range of external validity. Second, from this body of research, more coherent propositions may emerge delineating their respective range of application, both in space and time.

It seems likely that such medium-range theories increasingly will be based on regional and historical commonalities of certain countries and cultures. Some deep structures, such as the social cleavages in Western Europe, and deep cultures, such as certain characteristic submilieus in Germany or Italy, have persisted over centuries and can be linked to present developments (Putnam, 1993; Flora, 1999). What is needed are better qualitative and quantitative methods to assess their continuities and changes over time and dynamic concepts and tools to establish their interactions, not just in abstract theory but also in empirical reality.

Abstract

Randomized studies are the gold-standard way to study the effect of a treatment. However, many randomized studies suffer from noncompliance – some subjects do not comply with their assigned protocol. When there is noncompliance, researchers are often interested in estimating the effect of receiving the treatment. The difficulty is that who receives the treatment is not random when there is noncompliance because subjects self-select whether they comply with their assigned protocol. We discuss approaches for unbiasedly estimating the effect of the treatment, focusing particularly on the instrumental variable approach.

Introduction

In many randomized trials, some subjects do not comply with their assigned treatment protocol (see **Figure 1**). In this article, we will discuss what quantities are of interest to estimate when there is noncompliance in a randomized trial and how to estimate those quantities. For most of the article, we will focus on two-arm trials and then we will discuss multiarm trials at the end of the article. As an example, we will consider the PROSPECT study, a randomized trial of an intervention to improve treatment of depression among depressed elderly patients in primary care practices (Bruce et al., 2004). The intervention was that a depression care specialist collaborated with the patient's primary care physician to facilitate adherence to a depression treatment strategy and provide education and assessment to the patient. The control was usual care. The study involved 539 depressed patients in 20 primary care practices at 3 sites. Each practice was randomized to either intervention (the treatment) or usual care (the control). Compliance with the intervention was categorized as a binary variable, whether or not a patient had seen a depression care specialist in the 4 months after the beginning of the trial. The outcome of interest is the change in a patient's Hamilton depression scores from baseline to 4 months after the beginning of the trial. The Hamilton score takes values between 0 and 50, with a higher value meaning more depression; so a negative change in Hamilton depression score means that depression has been reduced.

The as-received treatment effect is the effect of receiving the experimental treatment (hereafter referred to as the 'treatment') relative to receiving the control condition (hereafter referred to as the 'control'). By contrast, the intent-to-treat (ITT) effect (**Figure 1**) is the effect of being offered the treatment relative to being offered the control. Both the as-received treatment effect and the ITT effect are valuable to know. One situation when knowing the as-received treatment effect is particularly valuable is when the treatment nonadherence pattern is expected to differ between the study sample and the target population (Sommer and Zeger, 1991; Sheiner and Rubin, 1995; Small et al., 2006). For example, in studies of psychiatric interventions like the PROSPECT study, the study sample may consist of physically healthy patients highly adherent to their psychiatric care whereas the target population may contain many people receiving multiple treatments for medical comorbidities who are less likely to adhere to psychiatric treatments, or intensive efforts to maintain high levels of adherence in randomized trials may not be able to be maintained by the community of practitioners without similar resources to sustain adherence among their patients (Ten Have et al., 2008). In this situation, the ITT estimate may be biased for the effect of offering the treatment to the target population (Sommer and Zeger, 1991; Sheiner and Rubin, 1995). A key quantity that needs to be known to accurately predict the effect of offering the treatment to the target population is the effect of actually receiving the treatment (Sheiner and Rubin, 1995; Small et al., 2006). As an example, Sommer and Zeger (1991) discuss a trial of vitamin A supplementation to reduce child mortality. In the trial, the vitamin A supplementation was implemented by having children take pills and some children who were randomized to treatment did not take the pills. The ITT effect is the effect of making vitamin A pills available to children. However, if the trial showed that taking the pills was efficacious, vitamin A supplementation would not likely be implemented by providing pills but instead by fortifying a daily food item such as monosodium glutamate or salt (Sommer and Zeger, 1991). By knowing the effect of receiving vitamin A supplementation (the biologic efficacy) and the rate at which vitamin A supplementation would be successfully delivered under a fortification program, we can estimate the effectiveness

Figure 1 Noncompliance in randomized studies. ITT, intent-to-treat. R, Randomization; AT, Always Takers.

of a fortification program. A second situation in which knowing the effect of receiving treatment versus control is particularly valuable is when patients who are interested in fully adhering to a treatment are making decisions about whether to take the treatment (Sheiner and Rubin, 1995; Hernán and Hernández-Díaz, 2012). For example, Hernán and Hernández-Díaz (2012) mention the setting that to decide whether to use a certain contraception method, a couple may want to know the failure rate if they use the method as indicated, rather than the failure rate in a population that included a substantial proportion of nonadherers.

A commonly used estimator for the as-received treatment effect is the as-treated estimate (**Figure 1**). The as-treated estimate is the difference between the mean outcome among patients who received the treatment and the mean outcome among patients who did not receive the treatment. In a trial in which only the assigned-to-treatment arm can receive the treatment, the as-treated estimate will be biased if patients who would adhere to the treatment if randomized to it (would be adherers) differ in their characteristics from those who would not adhere to treatment if randomized to it (would be nonadherers) because the as-treated estimate compares would be adherers to a mixture of would-be adherers and would-be nonadherers. A vivid example of how would-be adherers can differ from would-be nonadherers was provided by May et al. (1981) in their discussion of the Coronary Drug Project, a randomized trial of lipid-lowering drugs for individuals who had survived myocardial infarction. Good adherers in the group assigned to the lipid-lowering drugs had a 5-year mortality rate of 15.0% whereas poor adherers had a mortality rate of 24.6%, making the lipid-lowering drugs seem promising. However, in the placebo group, good adherers had a mortality rate of 15.1% and poor adherers had a mortality rate of 28.2%, so placebo looks even more promising. For cardiac patients, the would-be adherers might have better diet and exercise more than the would-be nonadherers, leading to better outcomes if both groups received the same treatment. In contrast, in psychiatry, there are examples in which the would-be adherers are less healthy than would-be nonadherers (Small et al., 2006; Ten Have et al., 2008).

The as-treated estimate may be biased for estimating the as-received treatment effect because of unmeasured confounding, e.g., individuals with better diet may be more likely to adhere to treatment and to have better outcomes regardless of treatment. Another standard estimate of the as-received treatment effect is the per-protocol estimate, which compares the outcomes of subjects who were assigned to the treatment and followed the treatment protocol to subjects who were assigned the control and followed the control protocol; similar to the as-treated estimate, the per-protocol estimate may be biased for estimating the effect of receiving the treatment because of unmeasured confounding, e.g., individuals with better diet may be more likely to adhere to treatment but all subjects may adhere with the control if the control is usual care. Instrumental variable (IV) methods are methods for adjusting the unmeasured confounding. In a randomized trial with nonadherence, the random assignment of being offered the treatment may be an IV that can be used to control for unmeasured confounding in estimating the as-received treatment effect. In the next section, we will discuss the IV approach.

IV Approach

Framework and Notation

The Neyman–Rubin potential outcomes framework (Neyman, 1990; Rubin, 1974) will be used to describe causal effects and formulate IV assumptions. The classic econometric formulation of IVs is in terms of structural equations and assumptions about the IV being uncorrelated with structural error terms; the formulation in terms of potential outcomes that is described here provides clarity about what effects are being estimated when there are heterogeneous treatment effects and provides a firm foundation for nonlinear as well as linear outcome models (Holland, 1988; Angrist et al., 1996). Suppose there are N subjects. Let $\mathbf{Z}$ denote the N-dimensional vector of treatment assignments with individual elements Z_i, $i = 1, \ldots, N$, where $Z_i = 0$ or 1; the treatment assignment Z will be the IV in a randomized study. Let $\mathbf{D}^{\mathbf{z}}$ be the N-dimensional vector of potential treatment received under treatment assignment $\mathbf{z}$ with elements $D_i^{\mathbf{z}}$, $i = 1, \ldots, N$, $D_i^{\mathbf{z}} = 1$ or 0 according to whether person i would receive treatment level 1 or 0 under treatment assignment $\mathbf{z}$. Let $\mathbf{Y}^{\mathbf{z},\mathbf{d}}$ be the N-dimensional vector of potential outcomes under treatment assignment $\mathbf{z}$ and treatment received $\mathbf{d}$ where $\mathbf{Y}_i^{\mathbf{z},\mathbf{d}}$ is the outcome subject i would have under treatment assignment $\mathbf{z}$ and treatment received $\mathbf{d}$. The observed treatment received for subject i is $D_i \equiv D_i^{\mathbf{Z}}$ and the observed outcome for subject i is $Y_i \equiv Y_i^{\mathbf{Z},\mathbf{D}^{\mathbf{Z}}}$. Let $\mathbf{X}_i$ denote observed covariates for subject i. When we write expressions like $E(Y)$, we mean the expected value of Y for a randomly sampled subject from the population.

Angrist et al. (1996) considered treatment assignment to be an IV if it satisfies five assumptions – the stable unit treatment value assumption (SUTVA), the IV is positively correlated with treatment assumption, the IV is independent of unmeasured confounders assumption, the exclusion restriction (ER) assumption, and the monotonicity assumption. We will describe the first four of these assumptions and then describe the need for the fifth assumption or some substitute to obtain point identification. The first four assumptions are:

IV-A1 *SUTVA*. If $\mathbf{z}_i = \mathbf{z}_i'$, then $D_i^{\mathbf{z}} = D_i^{\mathbf{z}'}$ and if $\mathbf{z}_i = \mathbf{z}_i'$ and $\mathbf{d}_i = \mathbf{d}_i'$, then $Y_i^{\mathbf{z},\mathbf{d}} = Y_i^{\mathbf{z}',\mathbf{d}'}$. In words, this assumption says that the treatment assigned and treatment received by a subject only affects that subject and not other subjects, and that there are not different versions of the treatment which have different effects (see Angrist et al., 1996; Rubin, 1990 for details). The SUTVA allows us to write $D_i^{\mathbf{z}}$ as D_i^{z} where z here denotes subject i having treatment assignment z, and $Y_i^{\mathbf{z},\mathbf{d}}$ as $Y_i^{z,d}$ where z and d here denote subject i having treatment assignment z and treatment received d.

IV-A2 *Treatment assignment is positively correlated with treatment received*. $E(D^1) > E(D^0)$.

IV-A3 *Treatment assignment is independent of baseline variables and unmeasured confounders*.

$$Z \perp \left(D^1, D^0, Y^{1,1}, Y^{1,0}, Y^{0,1}, Y^{0,0}\right)$$

IV-A4 *ER*. This assumption says that the treatment assignment affects outcomes only through its effect on treatment received: $Y_i^{z,d} = Y_i^{z',d}$ for all i. Under the ER, we can write $Y_i^d \equiv Y_i^{z,d}$ for any z, i.e., Y_i^1 is the potential outcome for subject i if he or she were to receive level 1 of the

treatment (regardless of his or her treatment assignment) and Y_i^0 is the potential outcome if he or she were to receive level 0 of the treatment. The ER assumption is also called the no-direct-effect assumption.

Assumptions IV-A2, IV-A3, and IV-A4 are the 'core' IV assumptions that basically all IV approaches make; assumption IV-A1 is typically implicitly made as well. Figure 2 shows a graphical model view with random treatment assignment as an IV. Assumption IV-A2 will be satisfied in a randomized trial as long as the treatment assignment provides some encouragement to take the treatment. Assumption IV-A3 will be satisfied in a randomized trial as long as the treatment was in fact randomly assigned. Assumption IV-A4 could be violated if the treatment assignment has some effect beyond its effect on treatment assignment. In a placebo-controlled randomized trial, assumption IV-A4 would be violated if the placebo has some beneficial effect and never-takers have some chance of taking the placebo under the control; then, the never-takers would have a higher average outcome under assignment to the control (where they might take the placebo) than under assignment to the treatment (where they will not take the placebo nor the treatment).

The core IV assumptions IV-A2, IV-A3, and IV-A4 enable bounds on treatment effects to be identified but do not point identify a treatment effect (Balke and Pearl, 1997). To see why the core IV assumptions alone do not point identify a treatment effect and to understand what additional assumptions would identify a treatment effect, it is helpful to introduce the idea of compliance classes (Angrist et al., 1996). A subject in a study with binary IV and treatment can be classified into one of four latent compliance classes based on the joint values of potential treatment received (Angrist et al., 1996). The four compliance classes are referred to as never-takers, always-takers, defiers, and compliers. We denote subject i's compliance class as C_i, which are defined like so: C_i = never-taker (nt) if $(D_i^0, D_i^1) = (0, 0)$, i.e., subjects who would never take the treatment regardless of the assignment; complier (co) if $(D_i^0, D_i^1) = (0, 1)$, i.e., subjects who would take the treatment if assigned to treatment and would not take the treatment if assigned to control; always-taker (at) if $(D_i^0, D_i^1) = (1, 1)$, i.e., subjects who would always take the treatment regardless of the assignment; and defier (de) if $(D_i^0, D_i^1) = (1, 0)$, i.e., subjects who would always take the opposite treatment to the assignment. Note that there being four compliance classes is not an assumption but an exhaustive list of the possible types of compliance. Note also that a subject's compliance class is relative to a particular randomized trial, e.g., a subject might be a complier in a trial which provided a strong incentive to adhere to the treatment if assigned to the treatment (e.g., financial incentives for adherence) but a never-taker in a trial without such incentives. Table 1 shows the relationship between the latent compliance classes and the observed groups.

From Table 1, each observed group ($Z_i = z$; $D_i = d$; $z, d = 0, 1$) is a mixture of two latent compliance classes. Treatment effects for the latent compliance classes will often be of interest. However, even under assumptions IV-A1 to IV-A4 such that both never-takers and always-takers would have the same potential outcome under treatment and control, we are not able to directly observe the outcomes for the latent compliance classes under treatment and control, and therefore not able to identify the effects for the latent compliance classes. For example, suppose the outcome is binary so that the observed data (Y, D, Z) are multinomial random variables with $2 \times 2 \times 2 = 8$ categories. Under assumptions IV-A1 to IV-A4, there are 10 free unknown parameters: $P(Z = 1)$, $P(Y^1 = 1|C = at)$, $P(Y^1 = 1|C = co)$, $P(Y^0 = 1|C = co)$, $P(Y^0 = 1|C = nt)$, $P(Y^1 = 1|C = de)$, $P(Y^0 = 1|C = de)$, $P(C = at)$, $P(C = co)$, and $P(C = nt)$ (note that $P(C = de)$ is determined by $P(C = co) + P(C = at) + P(C = nt) + P(C = de) = 1$). Since there are 10 free parameters but the observed data are multinomial random variables that have only 8 categories (so 7 free probabilities), the model is not identified. Two types of additional assumptions have been considered that reduce the number of free parameters: (1) an assumption about the process of selecting a treatment to take based on the treatment assigned that restricts the number of latent compliance classes by ruling out defiers and (2) assumptions that restrict the heterogeneity of treatment effects among the different compliance classes.

We first consider the approach (1) to point identification of restricting the number of compliance classes. The assumption made by Angrist et al. (1996) rules out defiers:

IV-A5 *Monotonicity assumption*. This assumption says that there are no subjects who are 'defiers,' who would only take level 1 of the treatment if not encouraged to do so, i.e., there is no subject i with $D_i^1 = 0$, $D_i^0 = 1$.

Monotonicity is automatically satisfied for single-consent randomized encouragement designs in which only the subjects assigned to receive the treatment are able to receive it (Zelen, 1979) (for this design, there are only compliers and never-takers). Monotonicity is also plausible in many randomized trials in which assignment to the treatment ($Z = 1$) provides a clear incentive and no disincentive to take the treatment. For

Table 1 The relation between observed groups and latent compliance classes

Z_i	D_i	C_i
1	1	Complier or always-taker
1	0	Never-taker or defier
0	0	Never-taker or complier
0	1	Always-taker or defier

Figure 2 Graphical model view of randomization as an IV.

examples of trials where monotonicity may not hold, see Ten Have et al. (2004). For the setting of a binary outcome, assumption IV-A5 reduces the number of free parameters to seven, enabling identification since there are seven free probabilities for the observed data. However, the model only identifies the average treatment effect for compliers. The never-takers and always-takers do not change their treatment status when the instrument changes, so under the ER assumption, the potential treatment and potential outcome under either level of the IV ($Z_i = 1$ or 0) are the same. Consequently, the IV is not helpful for learning about the treatment effect for always-takers or never-takers. Compliers are subjects who change their treatment status with the IV, that is, the subjects would take the treatment if they were encouraged to take it by the IV but would not otherwise take the treatment. Because these subjects change their treatment with the level of the IV, the IV is helpful for learning about their treatment effects. The average causal effect for this subgroup, $E(Y_i^1 - Y_i^0 | C_i = co)$, is called the complier average causal effect (CACE) or the local average treatment effect. It provides the information on the average causal effect of receiving the treatment for compliers.

Approach (2) to making assumptions about IVs to enable point identification of a treatment effect keeps assumptions IV-A1 to IV-A4 but does not make assumption IV-A5 (monotonicity); instead, it makes an assumption that restricts the heterogeneity of treatment effects among the compliance classes. The strongest such assumption is that the average effect of the treatment is the same for all the compliance classes, $E(Y^1 - Y^0 | C = co) = E(Y^1 - Y^0 | C = at) = E(Y^1 - Y^0 | C = nt) = E(Y^1 - Y^0 | C = de)$. This assumption identifies the average treatment effect for the whole population (this can be derived by using the same reasoning as in the derivation of eqn [2]). A weaker restriction on the heterogeneity of treatment effects among the compliance classes is the no current treatment value interaction assumption (Robins, 1994):

$$E(Y^1 - Y^0 | D = 1, Z = 1, \mathbf{X}) = E(Y^1 - Y^0 | D = 1, Z = 0, \mathbf{X}) \quad [1]$$

Assumption [1] combined with IV-A1 to IV-A4 identifies the average effect of treatment among the treated, $E(Y^1 - Y^0 | D = 1)$. Under assumptions IV-A1 to IV-A5, assumption [1] says that the average treatment effect is the same among always-takers and compliers conditional on $\mathbf{X}$, since the left hand side of eqn [1] is the average effect of treatment among compliers and always-takers, and the right hand side is the average effect among always-takers (all conditional on $\mathbf{X}$). For trials in which subjects cannot take the treatment if assigned to the control (e.g., single-consent randomized encouragement designs), approaches (1) and (2) are equivalent since in this case, there are no always-takers and the monotonicity assumption and eqn [1] hold by the design of the trial, and the average effect of treatment among the treated is equal to the average treatment effect among compliers. For further information on approach (2), see Tan (2010) and Vansteelandt et al. (2011).

We are going to focus on approach (1) to the IV assumptions (i.e., assumptions IV-A1 to IV-A5) for the rest of this article. An attractive feature of this approach is that the monotonicity assumption IV-A5 is reasonable in many applications (e.g., when assignment to treatment provides a clear incentive to take treatment and no disincentive). Although the effect identified by IV-A1 to IV-A5, the CACE, is only the effect for the subpopulation of compliers, the data are in general not informative about average effects for other subpopulations without extrapolation, just as a randomized experiment conducted on men is not informative about average effects for women without extrapolation (Imbens and Wooldridge, 2007). By focusing on estimating the CACE, the researcher sharply separates exploration of the information in the data from extrapolation to the (sub)population of interest (Imbens and Wooldridge, 2007). See Section Extrapolating the CACE to the Full Population for discussion of extrapolation of the CACE to other (sub)populations.

Two-Stage Least Squares (Wald) Estimator

Angrist et al. (1996) show that under assumptions IV-A1 to IV-A5, the CACE is nonparametrically identified by

$$\begin{aligned}
E(Y^1 - Y^0 | C = co) &= \frac{P(C = co)\left[E(Y^1 - Y^0 | C = co)\right]}{P(C = co)} \\
&= \frac{\left[P(C = at)E(Y^1 | C = at) + P(C = co)E(Y^1 | C = co) + P(C = nt)E(Y^0 | C = nt)\right] - \left[P(C = at)E(Y^1 | C = at) + P(C = co)E(Y^0 | C = co) + P(C = nt)E(Y^0 | C = nt)\right]}{\left[P(C = at) + P(C = co)\right] - \left[P(C = at)\right]} \\
&= \frac{\left[P(C = at)E(Y^{1,1} | C = at) + P(C = co)E(Y^{1,1} | C = co) + P(C = nt)E(Y^{1,0} | C = nt)\right] - \left[P(C = at)E(Y^{0,1} | C = at) + P(C = co)E(Y^{0,0} | C = co) + P(C = nt)E(Y^{0,0} | C = nt)\right]}{\left[P(C = at) + P(C = co)\right] - \left[P(C = at)\right]} \\
&= \frac{\left[P(C = at | Z = 1)E(Y^{1,1} | Z = 1, C = at) + P(C = co | Z = 1)E(Y^{1,1} | Z = 1, C = co) + P(C = nt | Z = 1)E(Y^{1,0} | Z = 1, C = nt)\right] - \left[P(C = at | Z = 0)E(Y^{0,1} | Z = 0, C = at) + P(C = co | Z = 0)E(Y^{0,0} | Z = 1, C = co) + P(C = nt | Z = 0)E(Y^{0,0} | Z = 0, C = nt)\right]}{\left[P(C = at | Z = 1) + P(C = co | Z = 1)\right] - \left[P(C = at | Z = 0)\right]} \\
&= \frac{E(Y | Z = 1) - E(Y | Z = 0)}{E(D | Z = 1) - E(D | Z = 0)}
\end{aligned} \quad [2]$$

where the second equality follows from the IV that is correlated with treatment-received assumption (assumption IV-A2), the third equality follows from the ER assumption (assumption IV-A4), the fourth equality follows from the IV that is independent of baseline variables and unmeasured confounders assumption (assumption IV-A3), and the last equality follows from the monotonicity assumption (assumption IV-A5) that the set of defiers is empty.

The standard IV estimator for a binary IV and a binary treatment is the sample analogue of the last expression in eqn [2],

$$\widehat{\text{CACE}} = \frac{\widehat{E}(Y_i|Z_i = 1) - \widehat{E}(Y_i|Z_i = 0)}{\widehat{E}(D_i|Z_i = 1) - \widehat{E}(D_i|Z_i = 0)} \qquad [3]$$

where $\widehat{E}$ denotes the sample mean. The standard IV estimator is called the Wald estimator after Wald (1940).

The standard IV estimator is also called the two-stage least squares (2SLS) estimator because it can be obtained from the following 2SLS procedure: (1) regress D on Z by least square to obtain$\widehat{E}(D|Z)$ and (2) regress Y on $\widehat{E}(D|Z)$. The coefficient on $\widehat{E}(D|Z)$ from the regression (2) equals eqn [3]. Since eqn [3] can be obtained by the 2SLS procedures, we denote eqn [3] by $\widehat{\text{CACE}}_{\text{2SLS}}$,

$$\widehat{\text{CACE}}_{\text{2SLS}} = \frac{\widehat{E}(Y_i|Z_i = 1) - \widehat{E}(Y_i|Z_i = 0)}{\widehat{E}(D_i|Z_i = 1) - \widehat{E}(D_i|Z_i = 0)} \qquad [4]$$

To see why 2SLS provides a consistent estimate of the CACE, write $Y = \alpha + \text{CACE} \times D + u$, where α is chosen so that $E(u) = 0$. Then, under the monotonicity and ER assumption,

$$\alpha + u_i = \begin{cases} Y_i^1 - \text{CACE} & C_i = at \\ Y_i^0 + \left[\left(Y_i^1 - Y_i^0\right) - \text{CACE}\right]Z_i & C_i = co \\ Y_i^0 & C_i = nt \end{cases}$$

Thus, under the assumption that the IV is independent of baseline variables and unmeasured confounders (IV-A3), $E(Y|Z) = \alpha + \text{CACE} \times E(D|Z)$ and an unbiased estimate of the CACE can be obtained from regressing Y on $E(D|Z)$. We do not know $E(D|Z)$ but can replace it by the consistent estimate $\widehat{E}(D|Z)$ from regressing D on Z, and then regress Y on $\widehat{E}(D|Z)$; this is the 2SLS procedure. The standard error for $\widehat{\text{CACE}}_{\text{2SLS}}$ is not the standard error from the second-stage regression but needs to account for the sampling uncertainty in using $\widehat{E}(D|Z)$ as an estimate of $E(D|Z)$; see White (1984), Davidson and MacKinnon (1993), Imbens and Angrist (1994), and Freedman (2009: Chapter 9.8). Specifically, the asymptotic standard error for $\widehat{\text{CACE}}_{\text{2SLS}}$ is given in Imbens and Angrist (1994: Theorem 3). The 2SLS estimator $\widehat{\text{CACE}}_{\text{2SLS}}$ can also be written as $\frac{\widehat{\text{Cov}}(Y,Z)}{\widehat{\text{Cov}}(D,Z)}$ (Davidson and MacKinnon, 1993).

The 2SLS estimator does not take into full account the structure in **Table 1** that the observed outcomes are mixtures of outcomes from different compliance classes. Imbens and Rubin (1997a,b) and Cheng et al. (2009a,b) develop approaches to estimating the CACE that use the mixture structure to improve efficiency. For example, Cheng et al. (2009b) develop an empirical likelihood approach that is consistent under the same assumptions as 2SLS but that provides substantial efficiency gains in some finite sample settings. Sobel and Muthén (2012) develop an approach that assumes that the compliers are a mixture of subjects who are not affected by the treatment and subjects who are affected by the treatment, and estimates the proportion of subjects who are not affected by the treatment.

Robust Standard Errors for 2SLS

When there is cluster assignment in the randomized trial, standard errors that are robust to clustering should be computed. For 2SLS, this can be done by using robust Huber–White standard errors (White, 1982). Code for computing robust Huber–White standard errors for IV analysis with clustering in R is given in Section Example: the PROSPECT Study.

Even when there is no clustering we recommend always using the robust Huber–White standard errors for 2SLS, as the nonrobust standard error's correctness requires additional strong assumptions about the relationships between the different compliance classes' outcome distributions and homoskedasticity while the robust standard error's correctness does not require these assumptions; see Imbens and Angrist (1994: Theorem 3) and Angrist and Pischke (2009: Section 4.2.1). Code for computing robust Huber–White standard errors without clustering in R is available in the ivpack package in R, using the command robust.se.

Treatment Effect on the Whole Distribution of the Outcome

In addition to the average effect (CACE) discussed above, knowledge of the causal effect of a treatment on the outcome distribution and its general functions can often provide additional insights into the impact of the treatment and therefore be of significant interest in many situations (Poulson et al., 2012). For example, in a study of the effect of school-subsidized meal programs on children's weight, both low weight and high weight are adverse outcomes; therefore, knowing the effect of the program on the entire distribution of outcomes rather than just average weight is important for understanding the impact of the program. For an individual patient deciding which treatment to take, the patient must weigh the effects of the possible treatments on the distribution of outcomes, the costs of the treatments, and the potential side effects of the treatments (Hunink et al., 2001). Therefore, making the best decision requires information on the treatment's effect on the entire distribution of outcomes rather than just the average effect because a patient's utility over outcomes may be nonlinear over the outcome scale (Karni, 2009; Pliskin et al., 1980). Hogan and Lee (2004), Saigal et al. (1999), and Sommers et al. (2007) provide examples in HIV care, neonatal care, and cancer care respectively.

Abadie (2002) provided the standard IV estimate on the counterfactual cumulative distribution functions (cdfs) of the outcome of compliers with and without the treatment:

$$\widehat{H}_{c1}(y)^{\mathrm{SIV}} = \frac{\widehat{E}\{1(Y_i \le y)D_i|Z_i = 1\} - \widehat{E}\{1(Y_i \le y)D_i|Z_i = 0\}}{\widehat{E}(D_i|Z_i = 1) - \widehat{E}(D_i|Z_i = 0)}$$

$$\widehat{H}_{c0}(y)^{\mathrm{SIV}} = \frac{\widehat{E}\{1(Y_i \le y)(1-D_i)|Z_i = 1\} - \widehat{E}\{1(Y_i \le y)(1-D_i)|Z_i = 0\}}{\widehat{E}\{(1-D_i)|Z_i = 1\} - \widehat{E}\{(1-D_i)|Z_i = 0\}} \quad [5]$$

However, these standard IV estimates of the potential cdfs for compliers may not be nondecreasing functions as cdfs should be (Abadie, 2002; Imbens and Rubin, 1997b). Furthermore, the standard IV approach does not make full use of the mixture structure implied by the latent compliance class model (see **Table 1**) and hence could be inefficient (Imbens and Rubin, 1997b). Instead, Imbens and Rubin (1997b) proposed a normal approximation and two multinomial approximations to the outcome distributions. However, the estimator based on a normal approximation could be biased when the outcomes are not normal, and for the approach based on multinomial approximations, a systematic approach for choosing the multinomial approximations is needed. Cheng et al. (2009a) adopted a density ratio model (Anderson, 1979) to relate the potential outcome densities of latent compliance classes by an exponential tilt model and then maximized the empirical likelihood for semiparametric estimates of potential outcome densities and cdfs. Their approach makes full use of the mixture structure implied by the latent compliance class model without parametric assumptions on the outcome distributions, takes into account the nondecreasing property of cdfs and can be easily computed from the data. Their method can be applied to general outcomes and general functions of outcome distributions. Cheng et al. (2009a) showed that their estimator has good properties and is substantially more efficient than the standard IV estimator eqn [5].

Example: The PROSPECT Study

Table 2 shows the data from the PROSPECT study. This study was a single-consent randomized trial in which people could only receive the treatment if assigned to it. Among the 253 people assigned to treatment, 18 (7.4%) did not take the treatment. The ITT estimate for the effect of the treatment is $-7.46 - (-3.93) = -3.53$, i.e., a reduction in depression of 3.53 Hamilton points. The as-treated estimate is $-7.58 - (-4.07) = -3.51$. The per-protocol estimate is $-7.58 - (-3.93) = -3.65$. The as-treated and per-protocol estimates may be biased because the people who adhere to treatment when assigned to it (compliers) may be different types of people than never-takers; in contrast, the IV estimate is not biased if these groups of people are different. The IV estimate is $\frac{-7.46-(-3.93)}{235/253} = -3.80$ with a 95% confidence interval of $(-1.95, -5.65)$. The relationship between the as-treated and IV estimates suggests that compliers would have less of an improvement in depression than never-takers if both groups are given usual care.

Software for computing IV estimates is available in R, SAS, and STATA. The following R code using the library ivpack computes the IV estimate and cluster robust standard errors (the cluster is practice):

```
> library(ivpack)
> ivmodel=ivreg(hamiltonchange ~ treatreceivem4, ~interven)
> cluster.robust.se(ivmodel, practice)
[1] "Cluster Robust Standard Errors"

t test of coefficients:

               Estimate Std. Error t value  Pr(>|t|)
(Intercept)    -3.92496    0.61022 -6.4320 3.022e-10 ***
treatreceivem4 -3.80461    0.94187 -4.0394 6.228e-05 ***
---
Signif. codes:  0 *** 0.001 ** 0.01 * 0.05 . 0.1   1
```

Cheng et al. (2009a) applied the method in Section Treatment Effect on the Whole Distribution of the Outcome to analyze the effect of the treatment in the PROSPECT study on the distribution of outcomes among compliers. The outcome distributions of compliers under treatment and control are significantly different ($P < 0.01$) and the treatment appears to have more of an effect on compliers with worse depression scores.

Censoring

For survival outcomes, a common complication is censoring. For example, one type of censoring is administrative censoring, which means that a subject survived until the end of the time window of the study. For estimating the effect of a treatment on a survival outcome using an IV, Robins and Tsiatis (1991) considered a structural accelerated failure time model and developed semiparametric estimators for this model. Joffe (2001) provided a good discussion of their approach and comparisons with other survival analysis methods. Loeys and Goetghebeur (2003) and Cuzick et al. (2007) considered a structural proportional hazards model in which the hazard of the potential failure time under treatment for a certain group of subjects is proportional to the hazard of the potential failure time under control for these same subjects. Both the structural accelerated failure time model and the structural proportional hazards model are semiparametric models, where the effect of

Table 2 Data from the PROSPECT study

Randomization assignment	*Treatment received*	*No. of People*	*Mean Hamilton change*
Control	Control	234	−3.93
Treatment	Control	18	−5.89
Treatment	Treatment	235	−7.58
Treatment	Control or treatment	18 + 235 = 253	−7.46
Control or treatment	Control	234 + 18 = 252	−4.07

the treatment on the distribution of failure times is modeled parametrically.

Baker (1998) extended the models and assumptions for discrete-time survival data and derived closed-form expressions for estimating the difference in the hazards at a specific time between compliers under treatment and control based on maximum likelihood. Baker's (1998) estimator is analogous to the standard IV estimator for a survival outcome. Nie et al. (2011) discussed this standard IV approach and parametric maximum-likelihood methods for the difference in survival at a specific time between compliers under treatment and control.

Let $S_{c1}(V)$, $S_{c0}(V)$, $S_{at}(V)$, and $S_{nt}(V)$ be the potential survival functions at time V of compliers in the treatment and control groups and of always-takers and never-takers respectively, $S_z(V)$ be the survival probabilities at time V for the group with assignment $Z = z$, and $S_{zd}(V)$ be the survival probabilities at time V for the group with assignment $Z = z$ and treatment received $D = d$. By **Table 1** and the monotonicity assumption IV-A5 that rules out defiers, the following holds:

$$\begin{aligned}
S_1(V) &= \pi_c S_{c1}(V) + \pi_{at} S_{at}(V) + \pi_{nt} S_{nt}(V),\\
S_{11}(V) &= \frac{\pi_c}{\pi_c + \pi_{at}} S_{c1}(V) + \frac{\pi_{at}}{\pi_c + \pi_{at}} S_{at}(V)\\
S_{10}(V) &= S_{nt}(V)\\
S_0(V) &= \pi_c S_{c0}(V) + \pi_{at} S_{at}(V) + \pi_{nt} S_{nt}(V),\\
S_{00}(V) &= \frac{\pi_c}{\pi_c + \pi_{nt}} S_{c0}(V) + \frac{\pi_{nt}}{\pi_c + \pi_{nt}} S_{nt}(V)\\
S_{01}(V) &= S_{at}(V)
\end{aligned}$$

Similar to the standard IV estimator for the CACE eqn [4], the standard IV estimator for the compliers difference in survival probabilities at time V under treatment versus control is the following, where $\widehat{S}_z(V)$ is the Kaplan–Meier estimator of the survival probability at time V for the group with assignment $Z = z$,

$$\widehat{S}_{c1}(V) - \widehat{S}_{c0}(V) = \frac{\widehat{S}_1(V) - \widehat{S}_0(V)}{\widehat{E}(D|Z = 1) - \widehat{E}(D|Z = 0)} \qquad [6]$$

In addition to IV-A1 to IV-A5, an additional assumption is needed to ensure that the estimator [6] is consistent for the compliers difference in survival probabilities at time V:

> Independence assumption of failure times and censoring times: *The distributions of potential failure times T and censoring times C are independent of each other. Type I censoring (i.e., censoring times are the same for all subjects) and random censoring are two special cases.*

Although the standard IV estimator [6] is very useful, it may give negative estimates for hazards and be inefficient because it does not make full use of the mixture structure implied by the latent compliance model. When the survival functions follow some parametric distributions, Nie et al. (2011) used the Expectation-Maximation (EM) algorithm to obtain the maximum likelihood estimate (MLE) on the difference in survival probabilities for compliers. However, the MLEs could be biased when the parametric assumptions are not valid. To address this concern, Nie et al. (2011) developed a nonparametric estimator based on empirical likelihood that makes use of the mixture structure to gain efficiency over the standard IV method while not depending on parametric assumptions to be consistent.

Missing Response Data

In addition to noncompliance, missing response data are a concern in many randomized studies. For example, Ferro et al. (1996) conducted a trial of methods for teaching breast self-examination (BSE) for breast cancer screening in which women were randomly assigned to either a standard treatment of receiving mailed information about BSE ($Z = 0$) or an enhanced treatment of attendance in a self-exam course in addition to receiving the mailed information ($Z = 1$). A woman was considered to have received the treatment if she attended the self-exam course. Of the women assigned the self-exam course, only 55% of the women actually attended the course. The primary outcome for the study was whether or not a woman practiced BSE 1 year after the beginning of the study, where the outcome was obtained from a mailed self-administered questionnaire. Only 65% of the women returned the questionnaire.

Frangakis and Rubin (1999) provide a method-of-moments estimate of the CACE when there are missing response data under two additional assumptions besides IV-A1 to IV-A5. Let $R_i^{z=1} = 1$ or 0 indicate whether or not subject i would respond if he or she were assigned to the treatment, and let $R_i^{z=0}$ indicate whether or not subject i would respond if he or she were assigned to the control. The two additional assumptions made by Frangakis and Rubin (1999) are (1) latent ignorability, which means that potential outcomes are independent of potential responses given a subject's compliance class, $(Y^1, Y^0) \perp\!\!\!\perp (R^{z=1}, R^{z=0})|C$ and (2) the response ER for never-takers and always-takers, which says that assignment to treatment versus control does not affect whether the subject will respond, i.e., $R^{z=1} = R^{z=0}$ if $C = at$ or nt. Frangakis and Rubin (1999) show that the usual 2SLS estimate of the CACE [4] is biased when there are missing response data but provide a consistent estimator under the additional assumptions (1) and (2). Mealli et al. (2004) discuss that sometimes, instead of assuming the response ER for always-takers and never-takers, it may be more reasonable to assume a response ER for compliers and always-takers, $R^{z=1} = R^{z=0}$ if $C = at$ or $C = co$, and provide a consistent estimator of the CACE under IV-A1 to IV-A5, latent ignorability, and the response ER for compliers and always-takers. Mealli et al. (2004) argue that in the breast cancer screening study mentioned above, the response ER for never-takers is not so plausible. Never-takers who were assigned to the new treatment and declined participation have explicitly refused to comply with their assigned (active) treatment which might induce them to refuse to respond to the posttest questionnaire in comparison to never-takers who receive the standard treatment and have not explicitly refused to comply with it. The response ER seems more plausible for compliers as compliers are willing to follow the protocol in their assigned treatment, making it more plausible that they would not be affected in their response behavior by that assignment. Chen et al. (2009) and Small and Cheng (2009) discuss other assumptions under which the CACE is identified when there are missing response data.

Sensitivity Analysis for Violations of Assumptions

Since most of the IV assumptions cannot be completely tested, in this section, we will discuss sensitivity analysis to examine how the estimate of treatment effect will change if a proposed IV violates the assumptions by certain magnitudes.

Sensitivity Analysis for the ER

There is sometimes uncertainty about whether the treatment assignment satisfies IV-A4, the ER. For example, in the PROSPECT study, even if the patient did not adhere to the treatment (i.e., never saw the depression specialist), the depression specialist's presence in a practice may have helped improve the treatment of depression in that practice by primary care physicians. Even in blinded studies, the ER may not hold. For example, among subjects considered not to have received the experimental treatment, those assigned to the intervention arm might have received a larger partial dose (although considered inadequate), while those assigned to the control arm might have received a smaller partial dose or no dose at all (Ten Have et al., 2008). To the extent that partial dose might lead to some benefits, not receiving treatment when assigned to treatment in the experimental arm might be better than not receiving treatment in the control arm. Conversely, if there is a placebo effect, then not receiving treatment in the experimental arm (which means one would not have benefited from a placebo effect) might be worse than not receiving treatment in the control arm (which means one might still have benefited from a placebo effect). In either case, the ER would be violated because assignment to the treatment impacts outcomes through a pathway other than treatment received.

We can carry out a sensitivity analysis for the impact of violations of the ER in the PROSPECT study as follows. A model for a direct effect of the treatment on never-takers is

$$\begin{aligned} Y_i^{z,d} &= \alpha + \beta d + \lambda z(1-d) + e_i \\ E(e_i|Z_i) &= 0 \end{aligned} \qquad [7]$$

The direct effect of being assigned to the treatment on never-takers is λ. Under model [7], a consistent estimate of and inferences for β can be obtained by carrying out a 2SLS analysis with $Y_i - \lambda(1 - Z_i)D_i$ as the outcome variable, D_i as the treatment variable, and Z_i as the IV. For the PROSPECT study, if $\lambda = -1$ so that a depression specialist's presence in a practice improves the treatment of depression by 1 Hamilton point for subjects who do not see the depression specialist, we estimate that the CACE is -3.73 with a 95% confidence interval of $(-1.87, -5.59)$; this compares to the estimate of -3.80 with a 95% confidence interval of $(-1.95, -5.65)$ when the ER holds. The IV results for the PROSPECT study are not highly sensitive to plausible departures from the ER.

Sensitivity Analysis for Violation of the Monotonicity Assumption

In the PROSPECT study, the monotonicity assumption IV-A5 cannot be violated because no one can take the treatment when assigned to the control. But in trials where it is possible to take the treatment if assigned to control or take the control if assigned to treatment, it is possible that the monotonicity assumption could be violated. Suppose that IV-A1 to IV-A4 hold but IV-A5, the monotonicity assumption, is violated. Then, the 2SLS estimate eqn [4] converges to the CACE plus a bias term (Angrist et al., 1996):

$$\begin{aligned} \widehat{\mathrm{CACE}}_{2\mathrm{SLS}} \xrightarrow{p} \mathrm{CACE} - \frac{P(C=de)}{P(C=co)-P(C=de)} \\ \times \left\{E\left[Y^1 - Y^0 \middle| C = de\right] - E\left[Y^1 - Y^0 \middle| C = co\right]\right\} \end{aligned} \qquad [8]$$

(this can be proved by considering the effect of violations of monotonicity in the derivation of eqn [2]). The bias due to violations of monotonicity is composed of two factors. The first factor, $-\frac{P(C=de)}{P(C=co)-P(C=de)}$, is related to the proportion of defiers and is equal to zero under the monotonicity assumption. The smaller the proportion of defiers, the smaller the bias will be from violations of the monotonicity assumption. However, if the IV is weak in the sense that the average effect of the IV Z on D is small, then even a few defiers could generate a large bias; the stronger the IV, the lesser sensitive the IV estimate is to violations of the monotonicity assumption (Angrist et al., 1996). The second factor, $E[Y^1 - Y^0|C = de] - E[Y^1 - Y^0|\ C = co]$, is the difference in the average treatment effect between defiers and compliers. If the average treatment effect is identical for defiers and compliers, violations of the monotonicity assumption generate no bias. The lesser variation there is in the average treatment effect among defiers and compliers, the smaller the bias from violations of the monotonicity assumption.

Extrapolating the CACE to the Full Population

As discussed in Section IV Approach, the IV method estimates the CACE, the average treatment effect for the compliers (i.e., $E[Y^1 - Y^0|C = co]$). The average treatment effect in the population is, under the monotonicity assumption, a weighted average of the average treatment effect for the compliers, the average treatment effect for the never-takers, and the average treatment effect for the always-takers:

$$\begin{aligned} E\left[Y^1 - Y^0\right] &= P(C = co)E\left[Y^1 - Y^0 \middle| C = co\right] + P(C = at) \\ &\times E\left[Y^1 - Y^0 \middle| C = at\right] + P(C = nt)E\left[Y^1 - Y^0 \middle| C = nt\right] \end{aligned}$$

The IV method provides no direct information on the average treatment effect for always-takers (i.e., $E[Y^1 - Y^0|\ C = at]$) or the average treatment effect for never-takers (i.e., $E[Y^1 - Y^0|C = nt]$). However, the IV method can provide useful bounds on the average treatment effect for the whole population if a researcher is able to put bounds on the difference between the average treatment effect for compliers and the average treatment effects for never-takers and always-takers based on subject matter knowledge. For example, suppose a researcher is willing to assume that this difference is no more than b. Then

$$\begin{aligned} E\left[Y^1 - Y^0 \middle| C = co\right] - b\left[1 - P(C = co)\right] \le E\left[Y^1 - Y^0\right] \\ \le E\left[Y^1 - Y^0 \middle| C = co\right] + b\left[1 - P(C = co)\right] \end{aligned} \qquad [9]$$

where the quantities on the left and right hand sides of eqn [9] other than b can be estimated as discussed in Section IV Approach and Imbens and Rubin (1997b), Hirano et al. (2000), and Cheng et al. (2009a). For binary or other bounded outcomes, the boundedness of the outcomes can be used to tighten bounds on the average treatment effect for the whole population or other treatment effects (Balke and Pearl, 1997; Cheng and Small, 2006). Qualitative assumptions, such as that the average treatment effect is larger for always-takers than compliers, can also be used to tighten the bounds, e.g., Cheng and Small (2006), Bhattacharya et al. (2008), and Siddique (2013).

In thinking about extrapolating the CACE to the full population, it is useful to think about how compliers' outcomes compare to always-takers' and never-takers' outcomes (Imbens and Wooldridge, 2007). The data provide some information about this. Specifically, we can compare

$$\begin{aligned} &E(Y^0|C = nt) \text{ vs } E(Y^0|C = co) \text{ and} \\ &E(Y^1|C = at) \text{ vs } E(Y^1|C = co) \end{aligned} \qquad [10]$$

Under IV-A1 to IV-A5, Abadie (2002) shows that the following are consistent estimates of the quantities in eqn [10] when there are no covariates: $\widehat{E}(Y^0|C = nt) = \widehat{E}(Y|D = 0, \ Z = 1)$, $\widehat{E}(Y^0|C = co) = \frac{\widehat{E}(Y(1-D)|Z=1) - \widehat{E}(Y(1-D)|Z=0)}{\widehat{E}(1-D|Z=1) - \widehat{E}(1-D|Z=0)}$, $\widehat{E}(Y^1|C = at) = \widehat{E}(Y|D = 1, Z = 0)$, and $\widehat{E}(Y^1|C = co) = \frac{\widehat{E}(YD|Z=1) - \widehat{E}(YD|Z=0)}{\widehat{E}(D|Z=1) - \widehat{E}(D|Z=0)}$; when there are covariates, the methods of Abadie (2003) or Hirano et al. (2000) can be used to estimate the quantities in eqn [10]. If compliers, never-takers, and always-takers are found to be substantially different in levels by evidence of a substantial difference between $E(Y^0|C = nt)$ and $E(Y^0|C = co)$ and/or between $E(Y^1|C = at)$ and $E(Y^1|C = co)$, then it appears much less plausible that the average effect for compliers is indicative of average effects for other compliance types. On the other hand, if one finds that potential outcomes given the control for never-takers and compliers are similar, and potential outcomes given the treatment are similar for compliers and always-takers, it is more plausible that average treatment effects for the groups are also comparable (Imbens and Wooldridge, 2007). For example, in the PROSPECT study described in **Table 2**, the mean change in Hamilton score for never-takers is estimated to be −5.89 and for compliers under control is −3.78. This difference in estimated changes in Hamilton scores between the compliance classes suggests that we should be cautious in extrapolating the CACE to the full population.

Predictors of Compliance

When there is noncompliance, it is often of interest to understand what the predictors of compliance or noncompliance are. We can compare the mean of a covariate for compliers to the mean for never-takers and always-takers. The mean of a covariate X_i among the compliers is the following under the IV assumptions IV-A1 to IV-A5, where f represents the probability mass function or probability density function,

$$\begin{aligned} E[X|C = co] &= \int x \frac{f(x|C = co)}{f(x)} f(x)\mathrm{d}x \\ &= E\left[X \frac{f(X|C = co)}{f(X)}\right] \end{aligned} \qquad [11]$$

where

$$\begin{aligned} \frac{f(x|C = co)}{f(x)} &= \frac{\frac{P(C=co|x)f(x)}{P(C=co)}}{f(x)} = \frac{P(C = co|x)}{P(C = co)} \\ &= \frac{E(D|Z = 1, \ X = x) - E(D|Z = 0, \ X = x)}{E(D|Z = 1) - E(D|Z = 0)} \end{aligned} \qquad [12]$$

We estimate $E(X|C = co)$ by estimating $\theta_i = \frac{f(X_i|C=co)}{f(X_i)}$ for $i = 1, \ldots, N$ based on eqn [12] (e.g., using logistic regression to estimate $E(D|Z, X)$ and then plugging into eqn [12]) and then taking the sample average of $X_i\theta_i$. For a binary characteristic X, eqn [11] simplifies to

$$P(X = 1)\left[\frac{E(D|Z = 1, X = 1) - E(D|Z = 0, X = 1)}{E(D|Z = 1) - E(D|Z = 0)}\right]$$

We can estimate the mean of X for always-takers and never-takers by $\widehat{E}(X|D = 1, \ Z = 0)$ and $\widehat{E}(X|D = 0, \ Z = 1)$ respectively.

For the PROSPECT study, there are only compliers and never-takers. **Table 3** shows that compliers are significantly more depressed at baseline than never-takers.

Multiarm Trials

Multiarm trials with noncompliance are common. Cheng and Small (2006) consider the setting of a treatment with three levels – control (0) and two active levels A and B, where A and B are not ordered by dose and some subjects may prefer A to B and some may prefer B to A. Subjects are randomly assigned to one of the three arms 0, A, and B, and then could either take the assigned treatment or not take it and receive the control (for the control arm, all subjects receive the control 0). The effect of treatment A versus control for subjects who would take treatment A if offered it (i.e., compliers with treatment A) is identified by analyzing only subjects who were either assigned to the control arm or the treatment A arm. But for this setting, Cheng and Small (2006) showed that the effect of treatment A for subjects who would take treatment A if assigned to it but not treatment B and the effect of treatment A for subjects who would take treatments A or B if assigned to A or B respectively are not point identified. However, the data provide information that can be used to narrow bounds on these treatment effects. These treatment effects are of interest for individuals making

Table 3 Comparison of the characteristics of compliers and never-takers. The *p*-value is for testing the null hypothesis that $E(X|C = co) = E(X|C = nt)$

X	$\widehat{E}(X\|C = co)$	$\widehat{E}(X\|C = nt)$	p-*value*
Baseline suicidal ideation	0.30	0.28	0.83
Age	70.15	74.11	0.10
White	0.74	0.83	0.34
Baseline Hamilton	19.08	13.83	<0.01

decisions about which treatment to take, e.g., for a very compliant subject who knows he or she would take either treatment A or B if offered, he or she would like to know whether treatment A or B is better among very compliant subjects like himself or herself; the treatment effects are also of interest for clinicians deciding which treatment to offer first and for health policy makers anticipating what would happen were the treatment(s) to be introduced into general practice in a setting in which compliance patterns are expected to differ from those of the trial (Cheng and Small, 2006).

Roy et al. (2008) consider the related setting of a randomized trial with two active treatments and noncompliance to each treatment. Roy et al. (2008) use compliance-predictive covariates to help obtain information on causal effects within compliance classes. Although these causal effects are not point identified without further assumptions, the effects are identified once a sensitivity parameter describing the correlation between a subject's compliance under the two treatment arms is specified.

Partial Compliance

We have considered compliance with a treatment to be all or none. In some studies, subjects may partially comply with the treatment. Jin and Rubin (2008), Bartolucci and Grilli (2011), and Ma et al. (2011) develop approaches for estimating the compliance class specific causal effects for these settings. These methods involve additional assumptions beyond IV-A1 to IV-A5 to deal with the more complicated setting. Another approach to deal with partial compliance is to consider assumptions about causal effects being homogeneous across different compliance classes. For example, consider the model that there is a constant effect of a unit of treatment β, e.g., $Y^d = Y^0 + \beta d$, where d represents the proportion of dose a subject takes, $0 \leq d \leq 1$. Then, under assumptions analogous to IV-A1 to IV-A4, 2SLS (i.e., regressing D on Z and then regressing Y on $\widehat{D}$) provides a consistent estimate of β (Holland, 1988). For approaches that make homogeneity assumptions that are weaker, see Robins (1994) and Tan (2010). Even if the treatment effect is not constant, the two-stage least estimator still converges to a weighted average of the effect of one unit changes in the treatment level as long as an extended monotonicity assumption holds (Angrist and Imbens, 1995). The extended monotonicity assumption is that $D_i^{z=1} \geq D_i^{z=0}$.

Abstract

This article addresses the question of how public compliance with the criminal law is cultivated and sustained. We first consider the empirical evidence for instrumental and normative modes of compliance and social regulation. After arguing that normative compliance with the criminal law is ethically and practically preferable to that secured by instrumental models of crime control, we outline some future directions of research into procedural justice and legitimacy.

According to Bottoms (2002) there are four types of explanation for compliance with authority in general and with the criminal law in particular: (1) prudential or self-interested calculations about the potential costs and benefits of punishment, which take into account the risks and costs of punishment; (2) normative considerations about the 'rights and wrongs' of non-compliance; (3) the impact of obstructive strategies, such as locking up offenders to prevent their reoffending, as well as locking up the targets of criminal attention, literally or metaphorically; and (4) habit.

This article addresses the question of how public compliance with the criminal law is cultivated and sustained. It is concerned neither with obstructive (incapacitative) explanations nor with habit – though the latter is arguably the best explanation for why so many of us break the law so infrequently, and one that is much ignored by criminologists (a notable exception being Wikström et al., 2012). Both these explanations are in a sense secondary, in that they presuppose (respectively) that something led to offending at such a level or rate that imprisonment was needed, or else created the habit of compliance with the law.

Our focus in this article is whether normative explanations for compliance – especially those that appeal to the legitimacy of institutions of justice (Tyler, 2006a,b, 2011a,b) – are better in explaining public attitudes toward law enforcement than those that simply invoke the rational calculations of *homo economicus*. Exploring the nature and impact of legal authority, we first consider the empirical evidence for instrumental and normative modes of compliance and social regulation. After describing procedural justice and legitimacy as one of the most effective ways of securing normative compliance with the criminal law – and after arguing that such compliance is ethically and practically preferable to that secured by instrumental models of crime control – we outline some future directions for procedural justice research in the context of compliance and legal authority.

Deterrence and Social Regulation

Legal systems generally seek to improve legal compliance by using threat and punishment aimed at deterring people from engaging in criminal behavior (Nagin, 1998). In public and political discourse answers to the question – why do people break the law? – typically revolve around the idea that crime occurs when the criminal justice system provides insufficient likelihood of punishment, or when insufficiently tough sentences are imposed. Mechanisms of coercive social control and credible risks of sanction hope to persuade the rational choice would-be offender that – while otherwise desirable – a criminal act is not worth the risk.

The argument driving deterrence strategies is threefold: that fear of possible future punishment leads to compliance with the law; that risk calculations are partly shaped by both the anticipated likelihood of punishment and by judgments about its severity; and that the focus is (and should be) on the power of legal authorities and institutions to shape behavior by threatening to deliver (or by actually delivering) negative sanctions for rule breaking. This way of viewing the relationship between legal authorities and citizens is referred to as the 'deterrence' or 'social control' model. It is this model of human behavior that (for better or for worse) currently dominates law and public policy.

At the heart of the deterrence model of compliance is rational choice theory. Derived from neoclassical economics (Blumstein et al., 1978), a simple deterrence model assumes that people calculate expected utilities by multiplying the probability of an outcome (e.g., getting caught for armed robbery or drunk driving) by its valence or impact and then balance the result against the benefits of crime (Paternoster, 2006) Rational self-interest is the motivational engine; if laws and sanctions are well calibrated then people will arrive at the conclusion that they should follow the law. It follows that to regulate behavior decision makers should adjust criminal sanctions to the required level; the expected losses associated with law breaking will then minimize the likelihood that people will break the law.

Yet, this is a costly and minimally effective system of social control. It is costly because it assumes the need to create and maintain a credible threat of punishment. People will only change their behavior when they feel that there is a reasonable risk of being caught and punished for wrongdoing. They will also try to hide their illegal behavior, so a system of surveillance

is needed to identify and deter wrongdoing. Such surveillance is often not possible, but even when it is possible, surveillance is costly and its magnitude of influence is at best weak. For instance, an authoritative recent review concluded that some studies have found that: "… punishment weakens compliance, some [have found] that sanctions have no effect on compliance, and some [have found] that the effect of sanctions depends on moderating factors" (Picquero et al., 2011: p. 1; see also Paternoster, 2006). When perceptions of the likelihood of being caught and punished do influence people's behavior, the effect seems to be relatively small. Social control strategies that are based exclusively on a deterrence model of human behavior have had at best limited success. Deterrence is a high-cost strategy that, at best, yields identifiable but weak results.

In fact, under the rational choice/deterrence model we would expect crime to be more appealing and more pervasive than it actually is. Legal systems have become increasingly punitive, but the likelihood of being caught and punished for most criminal behaviors remains very low, and often too low to offset the potential gains of law breaking. Despite this, most people continue to follow the law, most of the time, even if they would bear very little consequence for breaking it.

Normative Modes of Social Regulation

Asking why not people *break the law* but why people *obey the law* brings into sharp focus the fact that most individuals obey most laws most of the time because they think it is the right thing to do, or they have simply acquired the habit of doing so. Formal criminal justice is only one of many systems of social control, most of which have a significant normative dimension (Tyler, 2003; Tyler et al., 2007; Jackson et al., 2012a,b; Mazerolle et al., 2013). Moral norms are learnt in childhood, with greater or lesser success. Institutions like the family, schooling, and (in some countries) religion have an important part to play. Developments in later life may further support or erode these norms.

Importantly for the current article, a good deal of research supports the idea that perceptions of the legitimacy of the institutions of justice play a further role in normative compliance. A legitimate authority commands consent (a sense of obligation to obey) that is grounded in legality and moral validity (Tyler, 2006a,b; Hough et al., 2013a,b). Crucially, if legitimacy encourages people to self-regulate, this obviates the need for expensive and minimally effective deterrence strategies. Models of crime-control that recognize the importance of the legitimacy of justice institutions and the legal system may be more durable – and less costly to a society – than the coercive model that requires a credible deterrent threat. Legitimate institutions can avoid the cost, danger, and alienation that are associated with policies based on external rules underpinned by deterrent threat (Schulhofer et al., 2011).

How does legitimacy shape law-related behavior? The dominant account in the field focuses on consent and authorization. When citizens recognize the legitimacy of an institution, they believe that the institution has the right to prescribe and enforce appropriate behavior, and they feel a corresponding duty to bring their behavior in line with that which is expected. Kelman and Hamilton (1989) refer to legitimacy as 'authorization.' A person authorizes an authority to determine appropriate behavior within a given situation, and then feels obligated to follow the directives or rules that authority establishes. Importantly, the authorization of actions by authorities "seem[s] to carry automatic justification for them. Behaviorally, authorization removes the necessity of making judgments or choices. Not only do normal moral principles become inoperative but – particularly when the actions are explicitly ordered – a different type of morality, linked to the duty to obey superior orders, tends to take over" (Kelman and Hamilton, 1989: p. 16).

Numerous empirical studies have shown that legitimacy judgments predict compliance behavior even after adjusting for perceptions of the morality of a particular act and perceptions of the chances of getting caught (e.g., Sunshine and Tyler, 2003; Jackson et al., 2012a; Papachristos et al., 2012a; Tyler and Jackson, 2014). Perceptions of the legitimacy of the police and the law seem to lead to a respect for legal guidelines for action that dictates what behavior is appropriate and personally binding. These guidelines may not be perfectly aligned with everyone's moral system; we do not always agree with the moral force of each and every law. But legitimacy involves the public recognition that the social order needs a system of laws that generate compliance and respect above and beyond individual preferences. When people believe it is morally just to obey the law, then so long as they know that a particular act is illegal, it becomes by definition wrong to commit it. A different sort of morality has 'kicked in' – one that focuses on the morality of the law in a general, not specific, sense.

Procedural Justice

How do legal authorities generate and sustain legitimacy in the eyes of citizens? According to procedural justice theory, legal authorities build legitimacy by acting according to principles of procedural fairness (Tyler and Huo, 2002; Sunshine and Tyler, 2003; Tyler, 2006a,b; Hough et al., 2013a,b). On the one hand, fair and respectful treatment and neutral and objective decision making provides the moral validity that justifies their institutional position. People's judgments about the extent to which legal authority is just, fair, and valid are based in part on the degree to which individual justice agents wield their authority in just and fair ways.

On the other hand, the exercise of authority via the application of fair process – treating people in ways that are recognized to be fair, respectful, and legal, and making fair and neutral decisions – strengthens the social bonds between individuals and authorities. Procedural justice encourages not just the belief that institutions have "a just, fair, and valid basis of legal authority" (in the words of Papachristos et al., 2012: p. 417) but also identification with the group that the authority represents (typically assumed to be the state), as well as the internalization of the belief that one should follow the rules of the group (Sunshine and Tyler, 2003; Tyler and Huo, 2002; Tyler, 2006a, 2011a).

What is procedural justice? The two key issues affecting the generation of procedural justice are fairness of decision-making processes (i.e., processes that are neutral, transparent, and allow

voice or the active participation of all the involved parities) and fairness of interpersonal treatment, sometimes referred to as interactional justice (i.e., treatment with respect and dignity). A key element of procedural justice is the implementation of voice practices. Voice means providing opportunities for individuals to participate in decision-making processes. In situations of everyday disagreements and conflicts it is important to provide opportunities for individuals to state their case before decisions concerning them are made. Informal dispute resolution mechanisms are popular in part because participating in decision making allows people to voice their own personal concerns, stating what they think the issues involved are, making suggestions for how they should be handled. Such opportunities for voice need not involve a formal or elaborate mechanism. Studies of police street stops, for example, indicate that when officers provide people an opportunity to tell their side of the story before they take action, people are much more likely to feel fairly treated (Tyler and Huo, 2002).

The element of neutrality refers to making decisions based on the consistent application of rules based on proper procedure rather than on personal opinions or prejudices. The discretionary nature of the criminal justice system provides considerable opportunity for the capricious and arbitrary exercise of power, and for authorities to act based on personal prejudice and implicit bias. By being seen as acting according to rules and by applying those rules evenly across people and time, authorities are viewed as acting fairly. Moreover, treatment with respect and dignity is consistently one of the most important issues that concern people when they are dealing with authorities. When people feel demeaned or subjected to negative stereotypes, they view themselves as diminished as people and disrespected by authorities. Conversely, when authorities acknowledge people's rights and act with courtesy, they tend to feel fairly treated regardless of outcome. People are influenced by their inferences about the motivations of the authorities with whom they are dealing. If they feel that authorities are acting out of a sincere desire to do what is right, then they view the authorities as acting more fairly. Authorities communicate trust by giving people a chance to explain their concerns, showing that what they say is being considered, and explaining why and how decisions are made.

Future Directions of Research

The field of legitimacy and procedural justice has developed important insights about compliance with legal authority. But research continues, and below we outline what we believe to be four promising directions for future empirical inquiry.

Boundary Conditions for Procedural Justice and Legitimacy

As others have noted (e.g., Tankebe, 2009; Murphy and Cherney, 2012; Bradford et al., 2013; Sargeant et al., 2013), we need a better understanding of the boundary conditions of procedural justice and legitimacy in the context of criminal justice. Are there some contexts under which procedural justice and legitimacy become more or less important in compliance with criminal laws? (Note that there are parallels here to ongoing criminological work into the conditions under which deterrence and credible threat can be influential and the sorts of people who are motivated more by rational chance than by normative factors, see Picquero et al., 2011.)

Might legitimacy be more of a motivational force for deterring some types of offending than other types of offending? Legitimacy may be a more important influence on people's behavior with respect to the sort of 'everyday crimes' that straddle the line between more serious crimes and those that according to Karstedt and Farrall (2006: p. 1011) "… fall into a grey zone of legality and morality." Yet, a recent study linked perceived police legitimacy to certain types of self-reported violent behavior, i.e., carrying a gun and getting into a fight (Papachristos et al., 2012). More work is clearly needed on this issue.

Procedural justice and legitimacy may also be more important for some individuals. One possible moderating factor is one's identification with the superordinate group that the authority is representing (Huo et al., 1996; Smith et al., 1998). The identity relevant information contained in individuals' treatment by authorities may be more or less salient or meaningful to them depending on the nature and strength of preexisting group affiliations. For instance, procedural fairness may matter less to people with uncomplicated identification with the mainstream society that the police represent, since their status is not an issue (Sunshine and Tyler, 2003). Conversely, those on the margin of the group may pay relatively more attention to fairness since inclusion and status *is* an issue to them (De Cremer, 2002). People have varying psychological needs in relation to social groups, and people who have a greater need of 'belongingness information' (De Cremer and Tyler, 2005: p. 166) may place greater emphasis on fair treatment than those with less need of such information. Procedural fairness may also matter more in situations where group status is salient to actors. Greater salience increases their receptiveness to identify relevant messages (Prooijen et al., 2002), while lower salience (or lack of shared group membership) decreases receptiveness. Thus far, the extent to which group identity moderates and/or mediates the associations between procedural justice and legitimacy in real world setting is unclear (Bradford, 2012).

Another possible boundary condition is national context. Work on legitimacy originated in the US but has since successfully migrated to the UK, Australia, Israel, and some other countries. Studies have found that procedural justice is central to legitimacy and that legitimacy is a key predictor of various law-related behaviors. Round 5 of the European Social Survey – a comparative, cross-national survey that is particularly strong in its commitment to equivalence in terms of sampling, mode of interviewing, weighting, and measurement – also shows strong and consistent associations between procedural fairness and legitimacy (Hough et al., 2013a,b).

But in Ghana and South Africa, effectiveness seems to be at least as important a predictor of legitimacy as procedural justice. In these countries the basic social utility of police may be doubted more in the US or the UK. Under such conditions people may draw more heavily on their assessments of the effectiveness of the public police when forming their legitimacy judgments. In the US, UK, and Australia the essential social utility of the police is often taken as a given; people's response to

perceived crime problems is often not to blame the public police, nor to turn to alternative providers of policing services, but to call for a greater level of intervention *from* the police (Girling et al., 2000). It may be that a baseline assumption of police efficacy in the US, UK, and Australia opens up a greater space for procedural justice judgments, while at the same time dampening down variation in legitimacy linked to effectiveness judgments. In contexts like South Africa and Ghana, this baseline sense of effectiveness is still to be established, resulting in a comparatively greater emphasis on instrumental concerns about effectiveness. The broader historical backdrop is important. In the case of Ghana, Tankebe (2009: p. 1280) refers to "… the failure of successive postcolonial governments to embark on any genuine and meaningful democratic reforms of the Ghana police to build strong attachments between the police and the citizenry."

More Experimental Work

Because a good deal of the evidence on procedural justice and legitimacy is survey based, it is limited in its ability to isolate and test causal effects. Observational data of this kind allows one to model conditional correlations in the broader population, but the design has three main weaknesses: (1) there may be any number of confounding variables; (2) the arrow of causality can go both ways; and (3) the time ordering may be unclear.

There is a pressing need for more randomized controlled trials (RCTs) in the vein of Mazerolle et al. (2013). To estimate the causal effect of procedural justice, Mazerolle and colleagues randomized police officers conducting alcohol breath tests in Queensland, Australia into two test conditions. In the control group it was 'business as usual.' In the experimental group police officers followed a script based on principles of procedural justice. Compared to the control group, citizens in the experimental group were more satisfied with how they were treated, were more likely to believe that the police exercise legitimate authority, and reported being more likely to comply in the future.

While RCTs can estimate the causal impact of procedural justice on legitimacy and other accounts, field experiments are often limited in their ability to assess *exactly why* the treatment affects the outcome. There is thus a need for laboratory-based experiments to uncover the psychological mechanisms that link procedural justice, legitimacy, and law-related behavior. Traditionally, legitimacy has been connected to internalization, in which one willingly consents to the demands of legal authorities to obey the law because one accepts their right to dictate appropriate behavior and feels a corresponding duty to obey (Tyler, 2006a,b). As an influence on criminal behavior, internalization differs from compliance because of its normative rather that instrumental character.

But legitimacy may also influence law-related behavior through identification (especially if one includes 'normative alignment' in the definition of legitimacy, see Jackson et al., 2012a,b; Tyler and Jackson, 2014). Legal authorities make demands on citizens, most forcefully to obey the law, and according to Kelman's (2006) typology of social influence, legal authorities can draw upon people's motivations to avoid punishment, to internalize the moral value that it is right to obey the law (and to internalize other values, like it is wrong to steal), and to identify with certain societal roles and responsibilities. Identification refers to the idea that people are motivated to act in ways that satisfy a particular relationship because they draw value, worth, and status from that relationship. Conforming to the expectations of a social role shapes behavior because people want "to establish and maintain a satisfying self-defining relationship to another person or a group" (Kelman, 1958: p. 53). Conformity to the norms and values attached to the reciprocal–role relationship gives satisfaction not only because it agrees with the norms and values (one internalizes the values and act in ways that are intrinsically rewarding), but also because one gains value and worth from the self-defining relationship.

We recommend future lab-based studies to examine whether internalization and identification are two (mutually reinforcing) mechanisms by which procedural justice and legitimacy influence law-related behavior. How legal authorities treat individuals and make decisions conveys value, worth, and status to individuals within the wider group that the legal authorities represent (Tyler and Blader, 2003; Blader and Tyler, 2009). On this account, procedural justice leads not just to internalization of values (one of which is that it is right and proper to obey the law) but also to the merging of one's self-concept with the group and the adoption of reciprocal–role relationships. Drawing upon panel data from a national probability sample of Australians, for instance, Bradford et al. (2014a) found that social identity – identifying themselves as Australian and adopting one proper role of an Australian citizen, that is to be law abiding – mediated the association between procedural justice and perceptions of legitimacy. Procedural justice may encourage people to feel part of the system, to be normatively aligned with legal authorities, to be 'in it together,' and by extension, perhaps, to act accordingly. We need more work on identification as a mechanism of social influence linking procedural justice to law-related behavior.

Another possible mechanism links the effect of procedural justice to perceptions and experiences of power. Procedural justice operates in environments that are hierarchical by nature, and while the existence of hierarchy may be beneficial to authorities or social institutions, it is far riskier to subordinates. Consenting to authorities' power means that subordinates accept having less power, less control, and less choice over their circumstances. A new line of experimental work suggests that procedural justice can remove some of the threats inherent to having less power by changing subordinates' subjective perception of power in two important ways (Mentovich, 2012). First, procedural justice seems to *empower* subordinates – when treated fairly by an authority figure, subordinates experience themselves as having more autonomy and more power compared with when they are treated unfairly. Second, procedural justice seems to *equalize* power relations – the use of procedural justice causes the hierarchical power relations between subordinates and authorities to be seen more similarly to relations between equals. These effects have also been demonstrated in how citizens view their power in law enforcement settings and with regard to legal authorities (Mentovich, 2012). In describing their encounter with a police officer, for instance, citizens reported feeling more autonomous, more powerful, and more equal to the officer who treated them fairly compared with unfairly.

More experimental work in this vein may help our understanding of the role of procedural justice in fostering legitimacy and cooperation. Might power distance operate alongside internalization and identification to drive law-related behavior? One question is whether a sense of subjective empowerment is particularly conducive to public cooperation that, unlike obedience, is based on a sense of volition, choice, and the belief that one's action will make an impact. While disempowered subordinates are more likely to obey, those who are empowered are more likely to cooperate. And since empowerment is a positive psychological experience in and of itself, subjectively empowered citizens may continue to cooperate with the police simply since they view this experience as altogether positive. Conversely, while some degree of power inequality may be necessary in society, this can be difficult for the less powerful to accept, and it is easier for those who are in the lower side of the power ladder to accept arrangements that minimize power disparities to as large an extent as possible. We thus recommend experimental studies examine whether citizens – particularly those in democratic societies that are accustomed to relatively lower levels of power distance in relations to civic authorities – are more likely to legitimize systems and authorities that maintain a relatively minimal degree of power differentials over them.

Legitimacy as Dynamic and Interactive

Third, a recent theoretical paper expands upon the dynamic and interactive nature of legitimacy comprising claims to legitimacy from power-holders and audience reception of those claims (Bottoms and Tankebe, 2012). It certainly makes sense to study legitimacy over time as a dynamic interaction among power holders and subordinates. For example, one common comment about street stops is that a person who has been stopped repeatedly views an interaction differently from someone who has not. It may well be that, over time, the dynamic of such stops changes for both parties, in part based on the officer's changing sense of authority and power, and in part based on the citizen's reception of the officer's claims to power and authority. Understanding this dynamic requires longitudinal approaches of the type proposed by Bottoms and Tankebe. Longitudinal work would capture the citizen's sense of duty to authority, judgment of the morality of police action, and perceptions of the lawfulness of those actions. The same studies would also capture the officers' sense of power and authority, the moral values expressed in their actions, and the lawfulness of what they do and how they behave (cf Tyler et al., 2007; Bottoms and Tankebe, 2013; Jonathan-Zamir and Harpaz, 2014). Work is especially needed on the measurement of power-holders' beliefs about their own legitimacy and empirical insight into how and why these beliefs shape their subsequent behavior (see Bradford et al., 2014b, for a discussion of what might shape police officers attitudes toward different policing styles).

Integrating Procedural Justice Theory with Criminological Accounts of Compliance

Finally, drawing links to existing criminological frameworks into offending may advance our understanding of compliance and legal authority. Consider situational action theory (SAT). Locating individuals in the potentially criminogenic contexts within which they act, SAT helps us flesh out the way in which individual decisions about crime may be both structured and influenced by the actions of legal authorities (as well as many other factors). SAT sees intentional criminal acts as a subset of a wider universe of moral rule-breaking acts: "an act of crime is to intentionally break a prescription for behaviour stated in the law" (Wikström, 2006: p. 2). And importantly, for a person to commit a crime in a given situation, they must first perceive the criminal act to be an option; they then make a judgment about that option; and finally they must choose to act based on that judgment. Whether an actor sees a criminal act as an 'action alternative' is key. If – and only if – they perceive the possibility of crime in a given situation, then they must make a judgment is made based on this perception.

It is reasonable to speculate that people who perceive the police and other legal authorities to be legitimate are less likely to see crime as an action alternative. If they internalize the value that it is morally just to obey the law, an illegal act may not even cross their minds as an option, so deterrence may not even be a factor driving the action alternatives. Bringing insights from SAT into procedural justice theory may thus shed light on some quite complex relationships among legitimacy, morality, deterrence, and criminal behavior.

Another criminological account of compliance and offending centers upon the idea of collective efficacy. Sampson and colleagues (Sampson et al., 1997, 1999, 2002) have shown that neighborhoods characterized by deprived social and economic conditions are limited in their ability to control or supervise behavior (primarily that of young people), and that the statistical effects of concentrated disadvantage, residential stability, and population heterogeneity on violence (and perceived violence) are partly mediated by 'collective efficacy,' i.e., shared values and shared propensities for action. First, particular patterns of social and economic life shape the extent to which neighborhoods develop shared dispositions to feel and act, fostering social control, and cohesion. Second, significant variation in these shared propensities to act on behalf of the collective good, which is then related to levels of violence, as well as people's perceptions of violence in their locality.

A recent London-based study found that collective efficacy in a given neighborhood was strongly linked to residents' beliefs about police legitimacy – the police have the right to exercise legitimate authority in the eyes of local residents partly when the object and purpose of their power (to effect social order and control) is achieved in the everyday (Jackson et al., 2012b). Because of the 'fit' of the police to the activity of policing, the police organization garners legitimacy from the extent to which the establishment and reproduction of normative social order is strong (most palpable in the informal social control mechanisms that regulate most conduct, rather than the formal policing that steps in when informal controls have failed). People feel more obligated to obey officers when the local community seems well policed, and are more likely to feel that the police share their values when the neighborhood seems orderly and well regulated. Conversely, they question police power and authority – and begin to doubt the desirability of conferring police power and authority – when they perceive quotidian processes of social ordering to be failing.

Future work might examine whether people recognize and justify police power not only when the police wield this power in a fair way (i.e., procedural justice) but also when social order in their local neighborhood seems to be adequately maintained – that is, when the broader activity of 'policing' appears successful. It may be that collective efficacy exerts a downward pressure on crime not only through a direct influence of informal social control mechanisms, but also because it encourages people to legitimize the police (they seem to justify their power because policing is strong in their local neighborhood, cf Jackson and Sunshine, 2007; Jackson and Bradford, 2009). Legitimacy may then have a knock-on effect on compliance.

Final Words

In this article we have considered the research evidence for how legal authority can secure public compliance with the criminal law. Procedural justice theory is to date the best-evidenced theory explaining what generates legitimacy in criminal justice settings, and how legitimacy in turn influences law-related behavior. The lesson for policy is clear. A crime-control model driven by procedural justice in its structure, legislation, and day-to-day policing practice addresses dilemmas that are created by the tensions between crime-control models of the regulation of criminal behavior and due process ones, offering a resolution which privileges professional standards and the consolidation of institutional legitimacy over short-term goals of crime control.

But research continues and in this article we have recommended a broader integration with existing work on compliance and offending, more work on the boundary conditions of procedural justice and legitimacy, more experimental research into effects and mechanisms, and a new focus on the dialogues between power-holders and subordinates. These are exciting areas of research, with much to be done, and many important lines of inquiry to pursue.

Abstract

The morbidity compression hypothesis as formulated by James Fries asserts that the time spent in states of chronic illness and disability prior to death will be reduced. It is driven by prevention, improved living conditions, and healthier lifestyles. It will take place within the context of increased life expectancy, but it may also occur in case of life expectancy remaining unchanged or being reduced. Studies on general health and cognitive impairment are pointing toward shorter periods of illness and disability. For more specific diseases, such as myocardial infarction, cancers, and diabetes, the available evidence is still insufficient. It remains to be determined whether morbidity compression occurs in the whole population or whether some subgroups are more affected than others. The degree of morbidity compression will determine the future development of health care and welfare systems, thus it is a topic for basic research as well as for public health practice.

Introduction

Morbidity compression is a key issue of active aging in Western countries and the US. The future development of morbidity and longevity will determine the allocation of health care and the way how the elderly will be cared for in the coming decades. This article gives an account of the current state of knowledge on morbidity compression. Morbidity expansion and the dynamic equilibrium, as alternative formulations, will be introduced, but they are not in the focus of this article, as each of them requires a separate discussion.

The different ways how health outcomes are being measured will be introduced. It will be shown that morbidity compression is a rather complex phenomenon, and that the available measures are depicting it in a rather incomplete way. The evidence on morbidity compression and its explanations will be presented by considering mental, physical, and general health separately. The relationships with social structural factors will be considered in a separate paragraph, and the contribution will conclude with a general evaluation of the present state of knowledge and with an outline of future directions of research.

The Morbidity Compression Hypothesis

Compression of morbidity was introduced in 1980 (Fries, 1980). James Fries assumed that prevention, changes of living conditions, and socioeconomic factors are contributing to shifting the first onset of disease, aging, and disability to the later years of life. The periods of time spent in states of disability and impaired health will become shorter. He did not only refer to onsets occurring in the ripe old age, but also to diseases starting earlier in life, e.g., myocardial infarction or states of minimal morbidity beginning around the age of 50 years (Fries et al., 2011). The hypothesis was formulated against the backdrop of the assumption of a maximum biological life span (Fries, 2012). Fries assumed that morbidity compression may be one option to improve health in spite of having reached the upper end of life expectancy. Whether a maximum biological age does exist is a matter of debate, and there is evidence that such an assumption is difficult to prove. Instead, increasing life expectancy may be explained by better health status in old age (Vaupel, 2010). However, for morbidity compression this is not necessarily of central importance, as healthy life expectancy may also be extended without total life expectancy to increase. It may also occur if human life span remains constant, and also in case of falling life expectancy (Fries et al., 2011). Morbidity compression has become an issue because in most Western countries life expectancy is increasing by 3 months every year (Doblhammer et al., 2012). The segments of the population where life expectancy has increased were changing as dependent on the time periods considered. From the early twentieth century onward, the reduction of neonatal and infant mortality was the main driving force, after 1960 it was the life expectancy above the age of 60 years. In the last decades this development continued into old age (Crimmins and Beltran-Sanchez, 2011), and a substantial proportion of the centenarians are surviving in good health (Andersen et al., 2012). The health of the elderly is of vital societal importance as it determines the future development of the welfare and the health care systems, the associated costs, and the decision about whether the age of retirement can be postponed beyond the age of 65 years.

The driving forces of morbidity compression are located in the areas of prevention that can contribute to the reduction of lifetime morbidity in different ways:

Primordial prevention refers, e.g., to the risk factors leading to smoking. The target groups of interventions are mainly adolescents where different behavioral (Thrul et al., 2013) as well as structural measures are most likely to be effective. This may entail a changing social connotation of smoking as a habit, to strengthen self-confidence and resistance against nicotine-promoting advertising. In the last decades, in Germany for instance, these efforts had been successful as the proportion of smokers in the younger age-groups has decreased, although the proportions are differing by social group (Schulze and Lampert, 2006). *Primary prevention* is directed toward reducing disease risks by quitting smoking, doing exercise, reducing stress levels at work, or changing work environments in ways that the risk of specific diseases is reduced. *Secondary*

prevention is directed toward the early detection of diseases with a popular example being breast cancer screening. It does not prevent disease onsets, but they will be detected in earlier stages. As a result, the burden of disease will be reduced or complete cure may become more likely. Finally, *tertiary prevention* is directed toward reducing risks of deterioration in case of an existing disease. This refers to lifestyle changes in patients, e.g., with myocardial infarction, in order to prevent the recurrence of a second infarction or related conditions and to support the primary therapy.

Besides these rather patient-centered measures, macrolevel and structural factors are important for improving health and life expectancy. The level of gross national income and the economic development have turned out as important determinants of life expectancy and risks of specific diseases like stroke or myocardial infarction (Mackenbach and Looman, 2013; Sposato and Saposnik, 2012). These macrolevel influences are representing the impact of so-called secondary factors such as the average educational level of a country, standard of living, or investments into infrastructure (e.g., sanitation, quality of health care, and public health efforts) or prosperity (Vaupel, 2010).

Alternative Directions of Morbidity Development

Morbidity compression posits an optimistic view of the direction in which health will be developing to. In case of its confirmation, population health will improve, the growth of health care costs will be smaller than expected, and the planning of infrastructure for frail people will have to be reconsidered. There are, however, two alternative assumptions about the development of population-based morbidity. In 1977, Ernest Gruenberg (Gruenberg, 1977) formulated a more pessimistic view that became to be known as 'expansion of morbidity.' He assumed that the development of medical treatments and drugs, e.g., antibiotics or techniques, for curing potentially lethal infections has positive outcomes, but there are also unintended effects of medical and technical progress. As a result, the number of chronically ill patients will increase, and cure will not be possible, instead they will continue to suffer from impaired health. In effect, life expectancy will improve, but it will take its toll on healthy life years, thus leading to increasing costs of health care and prolonged disability. As an example, Gruenberg described the case of patients with atherosclerosis who some decades ago died of associated complications such as pneumonia, coronary occlusion, and ruptured arteries. Medicine was successful in preventing them, but the consequence was an increase of the number of chronically ill patients. Another example is severe congenital malformations of the heart. In the last decades, the proportion of patients surviving after surgical treatment has increased (Moons et al., 2010), but the largest share is due to patients with complex malformations that can only be treated by palliative surgery. The risks of early cardiac insufficiency are increasing with disease severity, resulting in manifestations in the early years of life (Norozi et al., 2006). In spite of the operations of congenital heart disease being successful and with patients' life expectancy increasing, this sort of progress is creating a growing number of patients who are in constant need of medical supervision and treatment (Moons et al., 2010).

A position between these two scenarios was formulated by Manton (Manton, 1982). It became to be known as 'dynamic equilibrium,' as it combines elements of the compression and the expansion hypothesis. According to Manton, reduced mortality rates are the result of improved medical care and more advanced treatment methods that do not lead to reduced onset rates, but to disease and disability states of lower severity, thus leading to improved quality of life and improved abilities to master everyday life (Manton, 2008). Apart from medical care these developments may at least in part be explained by improvements of nutrition, sanitation, and education. Manton found evidence for a dynamic equilibrium when studying certain developments in the United States, e.g., for cardiovascular diseases, arthritis, and obesity (Manton, 2008). In a recent study from New Zealand, functional limitations and healthy life expectancy were examined longitudinally. It was concluded that the development in this country may rather be described as a dynamic equilibrium (Graham et al., 2004).

The Assessment of Morbidity Compression

Studies on morbidity compression are not based on a consistent definition of the term 'morbidity.' Only a small number refers to manifest diseases that can be diagnosed on the basis of well-defined organic manifestations such as acute myocardial infarction, stroke, or diabetes mellitus. A broad range of measures of health impairments can be used as further end points: The activities of daily living (ADL) (Katz et al., 1970) or instrumental activities of daily living (IADL) (Lawton and Brody, 1969) are respondent-based measures for assessing impairments of everyday functioning. They are covering a wide variety of indicators pointing to physical health. For dementia or cognitive impairment a multitude of measurement approaches is used, ranging from recall tests (Langa et al., 2008) to screening instruments such as the Mini-Mental State Examination (Folstein et al., 1975). Subjective health is often used in large population-based surveys. It consists of only one item asking respondents to rate their present state of health, and responses are depicted on a five-point scale (DeBruin et al., 1996). This item turned out to be correlated with a large variety of health-related outcomes including the prediction of mortality. More complex and more specific are symptom lists such as the Short Form-36 (SF-36) (Jenkins and Wright, 1993) or the Symptom Checklist-90R (SCL-90R) (Derogatis, 1992). They were developed to cover a broad range of complaints and symptoms.

A final group of indicators refers to life expectancy as summary measures of population health. They can be used to evaluate the sum of all developments occurring in defined time periods with respect to their effects on morbidity and mortality. Healthy life expectancy and healthy life years are expressing the number of years that a person at a given age may expect to live in good health. These measures take age-specific mortality, morbidity, and functional health status into account (Salomon et al., 2012).

Evidence from Studies

Fries was not focusing on particular diseases as his thinking was primarily directed toward morbidity compression within the context of disability, frailty, or general health (Crimmins and Beltran-Sanchez, 2011), concepts that may rather be subsumed under the heading of multimorbidity. The compression thesis, in connection with the effects of lifestyle patterns, was examined by surveying a sample of female and male alumni with a mean age of 68 years who had completed their school education between 1939 and 1944 (Chakravarty et al., 2012). Data collection took place between 1986 and 1998. The study examined whether lifestyle factors, in particular smoking, body weight, and physical exercise, were associated with functional status and age of death. An index was created by counting the number of risk factors, resulting in the definition of three risk groups. It turned out that the average age of death was the same in all three groups (M = 76 years), without pronounced gender differences. The relative risk of death in respondents with high risks as compared to the participants with low risks was 1.9 times higher, and if lifestyle factors were considered, the difference between the two extreme groups amounted to a relative risk of 2.8. A detailed examination revealed that in the group with the healthiest lifestyle patterns the overall disability rate was the lowest, and changes toward a deterioration of health status and disabilities were closer to the date of death than was the case in the comparison groups. The authors interpreted these findings as a confirmation of the morbidity compression thesis. They concluded that preventive efforts toward changing modifiable risk factors will reduce the burden of disease and the need for long-term care before death. In a follow-up assessment the observation period of this study population was extended beyond the age of 90 years with a mean age of M = 85 years (Chakravarty et al., 2012). The risk factors continued to predict progression of disability and changes of mortality. In the most favorable as compared to the most disadvantaged risk group, mortality was postponed by 3.6–3.9 years, and disability was postponed by 8.2 years. A preventive orientation in life has more effects on illness and disability than on the risk of death, and these findings are in line with the morbidity compression hypothesis. The study has nevertheless some limitations as the responses were based on self-reports and had not been cross-validated. Problems of selectivity should have been addressed in more detail, as individuals with an unfavorable health status are more likely to refrain from participating in surveys (Heilbrun et al., 1991; Panser et al., 1994). In addition, the sample was recruited from a particular population as their educational level was high, and it remained unclear whether the effects of health-related lifestyles vary by factors that had not been taken into account.

Fries and colleagues conducted a second study that covered an observation period of 21 years (Chakravarty et al., 2008). They collected data from female and male members of running clubs and healthy controls. The data were collected by means of self-administered questionnaires, and in addition data on health-related lifestyles, exercise habits, as well as illness and disabilities were assessed. Dependent variables were illness, disability, and death. Causes of death were drawn from the National Death Index.

After 21 years, disability levels in controls were higher than in the runners group, although the differences were not very pronounced at the beginning. Over the whole study period these differentials were widening, and this refers both to subjects who completed the study as well as to those who dropped out. Over the study period it turned out that disability levels were lower in the runners group, and among those with disability the progression was slower. Significant degrees of disability rates emerged with an average time lag between the initial measurement and follow-up of 2.3 years in controls and 8.7 years in runners. In addition, mortality rates were lower in the latter group. The reduced rate of deaths was primarily due to reductions of cardiovascular mortality, but to a smaller degree also to other causes. Again, the authors are interpreting the results as a confirmation of the morbidity compression hypothesis, and they are recommending regular exercise and a healthy lifestyle.

Surveys are overestimating the health status of target populations because the willingness to participate in studies is reduced in case of impaired health, thus leading to inappropriate conclusions about population health. The use of administrative data is a possible way out, and this had been done in a study with US Medicare data (Willis et al., 2012). A sample of women and men was used for examining effects of cardiorespiratory fitness in midlife on the onset of eight chronic conditions (congestive heart failure, ischemic heart disease, stroke, diabetes mellitus, chronic obstructive pulmonary disease, chronic kidney disease, Alzheimer's disease, and cancers of the colon and the lung). Outcomes were recorded after the age of 70 years. It turned out that higher fitness in midlife was associated with a lower incidence of chronic conditions in later life. Apart from lower risks, the average age of onset was postponed to later periods of life while survival rates were not changed significantly.

Manton et al. (2008) combined data of six surveys with health care utilization data. Respondents were at least 65 years old, and the study also included the oldest individuals of 95 years and beyond. This study is particularly interesting because it covered a period between 1982 and 2004, i.e., 22 years, and in addition to questionnaires, data on physical performance (ADL and IADL) were collected in order to assess impairments of daily activities and frailty. For women as well as for men it was found that the younger cohorts experienced longer lives in a nondisabled state as compared to individuals born earlier. Cohort effects were observed that were most pronounced at the upper end of life. Again, authors were interpreting these findings as support of the morbidity compression hypothesis.

The evidence on morbidity compression with respect to manifest diseases is scarce. Age-standardized incidences of cardiovascular diseases were decreasing in the last years, and there was a constant trend toward a shift into higher age-groups (Doblhammer et al., 2012). The same development was reported for the US (Crimmins and Beltran-Sanchez, 2011), but for Germany, age-standardized mortality rates only are available. In the male population they were decreasing since 1981, and in the female population the same development was found since 1985. In East Germany decline started with a delay after 1989. Similar findings were reported for stroke where the survival rates were increasing continuously since the 1980s

(Doblhammer et al., 2012). There are also developments in the opposite direction. Changes in lifestyles need not necessarily go hand in hand with improvements of health. In all European countries and in the US the obesity rates have increased in the last decades, and the age of onset shifted into younger age-groups (Astrup, 2012; Seidell, 2000). High rates of obesity in the population along with onsets in lower age-groups are associated with increased risks of secondary diseases, in particular type-2 diabetes (Brinks et al., 2012). At least in this case it has to be determined to what extent decreased morbidity rates and improvements of medical treatment are compensated by the concomitants of obesity.

The studies presented so far were focusing on physical health, functional impairments, or frailty, thus pointing to the effects of health-related lifestyle factors. Another line of research has concentrated on morbidity compression in terms of subjective health and cognitive functioning. Subjective health is frequently assessed as an unspecific measure of impaired health or functioning, as an indicator of distress and adverse experiences (Jylhä, 2009). The WHO has recommended it for use in health interview surveys (DeBruin et al., 1996) at a national, as well as at an international level, for purposes of health-related comparisons between countries.

In Germany, data of the Socio-Economic Panel and of the microcensus were used as basis for examining morbidity compression. No data on manifest diseases were available, but data on days spent in hospital and subjective health were collected (Kroll and Ziese, 2009). Comparing different age cohorts, evidence was found that subjective health in women and men in the higher age-groups was improving over the years. There was also a constant trend toward chronic diseases being associated with decreasing levels of disability. Both results are in line with the thesis of morbidity compression.

Self-reported health outcomes were also examined for the Austrian population between 60 and 89 years of age. Data of four waves of the national microcensus were used covering the period between 1978 and 1998 (Doblhammer and Kytir, 2001). As no data on specific diseases as end points were available, subjective health was used. As reported for other countries, life expectancy increased over the observation period. It was concluded that the health of elderly Austrians had improved over the years while the length of time spent in bad health became shorter. The findings support the conclusion that an absolute compression of morbidity had taken place. This development accelerated in the years from 1978 to 1983 and from 1991 to 1998, while from 1983 to 1991, a transitory stagnation occurred.

Social Differences in Morbidity Compression

In the studies described so far the study populations were stratified by gender and age, and both are essential, because life expectancies are strongly dependent on them. This is however neglecting effects of social factors as it is a well-established finding that large social differences in morbidity and mortality do exist (Mackenbach, 2006; Mackenbach et al., 2008), and their relative effects are varying by the disease and by the indicator chosen (Braveman et al., 2011; Geyer et al., 2006). For the most frequently occurring diseases the highest risks are found in individuals with the lowest education, incomes, and occupational positions. These social differences are emerging in midlife and persist into old age, although the effects are then weakened. According to Fries, morbidity compression is mainly triggered by preventive behavior and favorable living conditions, and both factors are unequally distributed across society. Thus, it has to be examined whether morbidity compression follows a social gradient, being more prevalent and starting earlier in the groups that are better off, while in the others this will occur with a time lag, as demonstrated in many other domains (Rogers, 1995).

Research on morbidity compression that includes indicators of social stratification is rare. Only a few studies included them at all, but usually as control variables (Qiu et al., 2013). Langa et al. (2008) used data of nationally representative samples from the US (N = 7406 and N = 7104) 70 years of age and older. They compared cohort effects of education on cognitive impairments. It turned out that the proportion of respondents with impairments dropped from 12.2% in 1993 to 8.7% in 2002, and higher mortality rates were found in respondents with higher degrees of cognitive impairment. The general level of education was higher in the cohort born later, and higher education was associated with lower morbidity levels.

Another study with respondents over 65 years of age covered a period of 16 years (Marioni et al., 2012). It examined whether cognitive activities, education, occupation, and social engagements were related to different levels of cognitive impairment. It turned out that cognitive, social, as well as intellectually demanding activities were related to better functioning. Expressed in quantitative terms, a man of 65 years of age with a low education, a low occupational position, and no marked social activities had an estimated residual life expectancy of 12.8 years with cognitive impairment and 8.5 years without cognitive impairment. At the opposite side are individuals with a high education, a high occupational position, and with social activities. Their life expectancy was 15.9 years, and they could expect 14.3 years without cognitive impairment. The figures of the female respondents are similar, thus the associations are holding both for women and men.

Taken together, educational level and favorable material conditions were associated with better cognitive functioning, and each indicator had independent effects. In both studies the authors explained the effects of education with reference to the cognitive reserve hypothesis (Whalley et al., 2004).

Concluding Remarks

The main goal of this article was to summarize the current evidence on morbidity compression. The empirical findings were structured along the three lines: cognitive impairments, specific diseases, and general measures of health. Studies have demonstrated that the time of life spent with cognitive impairments has decreased (Chakravarty et al., 2012; Doblhammer et al., 2013), and some found that this may also apply to dementia (Qiu et al., 2013). Studies dealing with general health (Chakravarty et al., 2008; Doblhammer and Kytir, 2001; Kroll and Ziese, 2009) reached the same conclusion. For myocardial infarction and other frequently occurring diagnoses there is evidence that morbidity compression may

occur, but the number of studies is still small. It is, however, not clear what will happen if the average age at the onset of chronic conditions is increasing, i.e., these disorders may then be replaced by other degenerative diseases, such as dementia. A more complete picture will emerge if the whole range of morbidity is taken into account.

Future studies should not only consider general concepts, such as cognitive impairment, general health, or disability, instead they should be differentiated by the type of disease. This refers to the most frequently occurring ones, notably myocardial infarction, stroke, malignant diseases, and diabetes. Disease-specific studies will also enable professionals to tailor preventive measures for higher age-groups. The next line of research refers to differentiated analyses of subpopulations, as in most studies conducted so far populations were differentiated only by gender and age. In studies on cognitive functioning, the samples were differentiated by indicators of socioeconomic position (Cagney and Lauderdale, 2002; Langa et al., 2008; Marioni et al., 2012) or by cultural background (Cagney and Lauderdale, 2002). It will be of interest to know whether morbidity compression is developing in the same way over the whole of a social structure, and whether some parts of the population are profiting more or less from it. Finally, the studies discussed so far were conducted mainly in Europe and in the US. Morbidity compression may however not be a universal finding as an international comparison of 187 countries concluded that healthy life expectancy was developing into different directions. In any case research on these topics is still at the beginning.

Computation: Expectation-Maximization Algorithm

Geoffrey J McLachlan, University of Queensland, Brisbane, QLD, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The EM (Expectation–Maximization) algorithm is a general-purpose algorithm for maximum likelihood estimation in a wide variety of situations best described as *incomplete-data* problems. On each iteration of the EM algorithm, there are two steps – called the *Expectation step* or the E-step and the *Maximization step* or the M-step. Because of this, the algorithm is called the EM algorithm. Often in practice the log likelihood function cannot be maximized analytically. In such cases, it may be possible to compute iteratively the maximum likelihood estimate using a Newton–Raphson maximization procedure or some variant, provided the total number of parameters in the model is not too large. Another possible alternative is to apply the EM algorithm, which is typically simpler to implement.

Introduction

The expectation–maximization (EM) algorithm is a broadly applicable approach to the iterative computation of maximum likelihood (ML) estimates. It is useful in situations where algorithms such as the Newton–Raphson method may turn out to be more complicated. On each iteration of the EM algorithm, there are two steps – called the *Expectation step* or the E-step and the *Maximization step* or the M-step. Because of this, the algorithm is called the EM algorithm. This name was given by Dempster et al. (1977) in their fundamental paper. Hereafter we refer to this paper as the DLR paper or simply DLR.

The basic idea of the EM algorithm is to view the problem of computing the ML estimates (MLEs) from the data at hand as being computationally simpler if data had been observed also on some other random variables. Thus with the EM algorithm the observed data are viewed as being incomplete, and the problem is reformulated in a complete-data framework in which the ML solution may exist in closed form or may be amenable to ML computation with a standard computer package.

In order to carry out estimation within the complete-data framework, there is the need to address the existence of the additional data (referred to as the 'missing' data). The EM algorithm does this in a way that is closely related to the ad hoc approach to estimation with missing data, where the parameters are estimated after filling in initial values for the missing data. The latter are then updated by their predicted values using these initial parameter estimates. The parameters are then reestimated, and so on, proceeding iteratively until convergence. With the EM algorithm, the 'missing data' are handled by taking the conditional expectation of the complete-data log likelihood given the observed data, using the current estimate of the unknown parameter vector. This is the so-called E-step and it yields the Q-function $Q\left(\boldsymbol{\Psi}; \boldsymbol{\Psi}^{(k)}\right)$, where $\boldsymbol{\Psi}$ is the vector of unknown parameters and $\boldsymbol{\Psi}^{(k)}$ is its current estimate. The M-step then updates the estimate of $\boldsymbol{\Psi}$ to $\boldsymbol{\Psi}^{(k+1)}$ by choosing $\boldsymbol{\Psi}$ to globally maximize $Q\left(\boldsymbol{\Psi}; \boldsymbol{\Psi}^{(k)}\right)$ over $\boldsymbol{\Psi}$.

As the above idea behind the EM algorithm is intuitive and natural, algorithms like the EM have been formulated and applied in a variety of problems even before the DLR paper. But as pointed out by McLachlan and Krishnan (2008), it was in the seminal DLR paper that the "ideas were synthesized, a general formulation of the EM algorithm established, its properties investigated, and a host of traditional and nontraditional applications indicated." The situations where the EM algorithm can be applied include not only evidently incomplete-data situations, where there are missing data, truncated distributions, censored or grouped observations, but also a whole variety of situations where the incompleteness of the data is not all that natural or evident. These include statistical models such as random effects, mixtures, convolutions, log linear models, and latent class and latent variable structures (McLachlan and Krishnan, 2008).

Early EM History

The earliest reference to literature on an EM-type of algorithm is Newcomb (1886), who considered estimation of parameters of a mixture of two univariate normals. McKendrick (1926) gave a medical application of a method in the spirit of the EM algorithm. Hartley (1958) gave a treatment of the general case of count data and enunciates the basic ideas of the EM algorithm. In a series of papers starting with Baum and Petrie (1966), Baum and colleagues dealt with an application of the EM algorithm in a Markov model. Orchard and Woodbury (1972) introduced the missing information principle, which is very much related to the spirit and basic ideas of the EM algorithm and note the general applicability of the principle. The relationship between the complete- and incomplete-data log likelihood functions established by Orchard and Woodbury (1972) leads to the fact that the MLE is a fixed point of a certain transform. Efron (1967) introduced the so-called self-consistency principle in a nonparametric setting for a wide class of incomplete-data problems as an intuitive analog of the ML principle and introduced the self-consistency algorithm for right-censored problems.

Prior to the appearance of the DLR paper, the resolution of mixtures of distributions for a variety of situations and distributional families gave rise to a number of algorithms that can be regarded as particular applications of the EM algorithm. These papers, which were surveyed in McLachlan (1982), McLachlan and Basford (1988), and McLachlan and Peel (2000), include

the seminal paper of Day (1969). Also, McLachlan (1975, 1977) proposed an iterative method for forming the (normal theory-based) linear discriminant function from partially classified training data.

Sundberg (1974, 1976) dealt with properties of the likelihood equation in the general context of incomplete-data problems from exponential families, and arrived at special forms for the likelihood equation and the information matrix, which have come to be known as Sundberg formulas. Sundberg (1976) acknowledged that his key 'iteration mapping,' which corresponds to the EM mapping of DLR, was suggested to him by A. Martin-Löf in a personal communication in 1967. Beale and Little (1975) developed an algorithm and the associated theory for the multivariate normal case with incomplete data.

For a more detailed account of the EM algorithm both before and after the DLR paper, the reader is referred to McLachlan and Krishnan (2008), the first edition of which appeared 20 years after DLR, and its second edition, which appeared just over 10 years later in 2008. In other publications devoted to the EM algorithm, there is the paper by Meng and van Dyk (1997), who read a paper to the Royal Statistical Society to celebrate the 20th anniversary of the presentation of the DLR paper. In their paper, after a brief historical account, strategies were investigated that aim to make the EM algorithm converge faster while maintaining its simplicity and stability (for example, automatic monotone convergence in likelihood). In another publication to celebrate the 20th anniversary of the DLR paper, there is the special issue of the journal *Statistical Methods in Medical Research* focused on the impact of the EM algorithm on medical statistics (McLachlan, 1997). In this issue, Meng (1997) provides a fascinating account of the work by McKendrick (1926) and its link with the EM algorithm. He also illustrates the central ideas underlying the EM algorithm and suggests ways for speeding up the algorithm. Meng (2007) in an article entitled "Thirty Years of EM and Much More" points out how EM and Markov chain Monte Carlo (MCMC) are intimately related, and that both have been 'workhorses for statistical computing.'

Before we proceed to give a formal definition of the EM algorithm, we introduce some notation and give a brief introduction to ML estimation.

Maximum Likelihood Estimation

We let $\boldsymbol{Y}$ be a p-dimensional random vector with probability density function (p.d.f.) $g(\boldsymbol{y}; \boldsymbol{\Psi})$ on $\mathbb{R}^p$, where $\boldsymbol{\Psi} = (\Psi_1, \ldots, \Psi_d)^T$ is the vector containing the unknown parameters in the postulated form for the p.d.f. of $\boldsymbol{Y}$. Here the superscript T denotes the transpose of a vector or a matrix. The parameter space is denoted by $\boldsymbol{\Omega}$. Although we are taking $\boldsymbol{Y}$ to be a continuous random vector, we can still view $g(\boldsymbol{y}; \boldsymbol{\Psi})$ as a p.d.f. in the case where $\boldsymbol{Y}$ is discrete by the adoption of counting measure.

For example, if $\boldsymbol{w}_1, \ldots, \boldsymbol{w}_n$ denotes an observed random sample of size n on some random vector W with p.d.f. $f(\boldsymbol{w}; \boldsymbol{\Psi})$, then

$$\boldsymbol{y} = \left(\boldsymbol{w}_1^T, \ldots, \boldsymbol{w}_n^T\right)^T$$

and

$$g(\boldsymbol{y}; \boldsymbol{\Psi}) = \prod_{j=1}^{n} f\left(\boldsymbol{w}_j; \boldsymbol{\Psi}\right)$$

The vector $\boldsymbol{\Psi}$ is to be estimated by maximum likelihood. The likelihood function for $\boldsymbol{\Psi}$ formed from the observed data $\boldsymbol{y}$ is given by

$$L(\boldsymbol{\Psi}) = g(\boldsymbol{y}; \boldsymbol{\Psi})$$

An estimate $\widehat{\boldsymbol{\Psi}}$ of $\boldsymbol{\Psi}$ can be obtained as a solution of the likelihood equation

$$\partial L(\boldsymbol{\Psi}/\partial \boldsymbol{\Psi}) = 0$$

or equivalently,

$$\partial \log\ L(\boldsymbol{\Psi})/\partial \boldsymbol{\Psi} = 0 \qquad [1]$$

Briefly, the aim of ML estimation (Lehmann, 1983) is to determine an estimate for each n ($\widehat{\boldsymbol{\Psi}}$ in the present context), so that it defines a sequence of roots of the likelihood equation that is consistent and asymptotically efficient. Such a sequence is known to exist under suitable regularity conditions (Cramer, 1946). With probability tending to one, these roots correspond to local maxima in the interior of the parameter space. For estimation models in general, the likelihood usually has a global maximum in the interior of the parameter space. Then typically a sequence of roots of the likelihood equation with the desired asymptotic properties is provided by taking $\widehat{\boldsymbol{\Psi}}$ for each n to be the root that globally maximizes the likelihood; that is, $\widehat{\boldsymbol{\Psi}}$ is the MLE. We shall henceforth refer to $\widehat{\boldsymbol{\Psi}}$ as the MLE, even though it may not globally maximize the likelihood. Indeed, in some of the examples on mixture models to be presented, the likelihood is unbounded. However, for these models there may still exist under the usual regularity conditions a sequence of roots of the likelihood equation with the properties of consistency, efficiency, and asymptotic normality; see McLachlan and Basford (1988, Chapter 1).

Although we are focusing here on the EM algorithm for computing MLEs in a frequentist framework, it can be equally applied to find the mode of the posterior distribution in a Bayesian framework.

Formulation of EM Algorithm

We let $\boldsymbol{Y}$ be the random vector corresponding to the observed data $\boldsymbol{y}$, having p.d.f. postulated as $g(\boldsymbol{y}; \boldsymbol{\Psi})$, where $\boldsymbol{\Psi} = (\Psi_1, \ldots, \Psi_d)^T$ is a vector of unknown parameters with parameter space $\boldsymbol{\Omega}$. The EM algorithm provides an iterative procedure for computing MLEs in situations where, but for the absence of some additional data, ML estimation would be straightforward. Hence in this context, the observed data vector $\boldsymbol{y}$ is viewed as being incomplete and is regarded as an observable function of the so-called complete-data. The notion of 'incomplete data' includes the conventional sense of missing data, but it also applies to situations where the complete data represent what would be available from some hypothetical experiment. In the latter case, the complete data may contain some variables that are never observable in a data sense. Within this framework, we let $\mathbf{x}$ denote the vector containing the augmented or so-called complete data,

and we let $\mathbf{z}$ denote the vector containing the additional data, referred to as the unobservable or missing data.

Even when a problem does not at first appear to be an incomplete-data one, computation of MLE is often greatly facilitated by artificially formulating it to be as such. This is because the EM algorithm exploits the reduced complexity of ML estimation given the complete data. For many statistical problems the complete-data likelihood has a nice form.

We let $g_c(\mathbf{x}; \mathbf{\Psi})$ denote the p.d.f. of the random vector $\mathbf{X}$ corresponding to the complete-data vector $\mathbf{x}$. Then the complete-data log likelihood function that could be formed for $\mathbf{\Psi}$ if $\mathbf{x}$ were fully observable is given by

$$\log\ L_c(\mathbf{\Psi}) = \log\ g_c(\mathbf{x}; \mathbf{\Psi})$$

Formally, we have two sample spaces $\mathcal{X}$ and $\mathcal{Y}$ and a many-to-one mapping from $\mathcal{X}$ to $\mathcal{Y}$. Instead of observing the complete-data vector $\mathbf{x}$ in $\mathcal{X}$, we observe the incomplete-data vector $\mathbf{y} = \mathbf{y}(\mathbf{X})$ in $\mathcal{Y}$. It follows that

$$g(\mathbf{y}; \mathbf{\Psi}) = \int_{\mathcal{X}(\mathbf{y})} g_c(\mathbf{x}; \mathbf{\Psi})\mathrm{d}\mathbf{x}$$

where $\mathcal{X}(\mathbf{y})$ is the subset of $\mathcal{X}$ determined by the equation $\mathbf{y} = \mathbf{y}(\mathbf{X})$.

The EM algorithm approaches the problem of solving the incomplete-data likelihood eqn [1] indirectly by proceeding iteratively in terms of the complete-data log likelihood function, $\log L_c(\mathbf{\Psi})$. As it is unobservable, it is replaced by its conditional expectation given $\mathbf{y}$, using the current fit for $\mathbf{\Psi}$.

More specifically, let $\mathbf{\Psi}^{(0)}$ be some initial value for $\mathbf{\Psi}$. Then on the first iteration, the E-step requires the calculation of

$$Q\left(\mathbf{\Psi}; \mathbf{\Psi}^{(0)}\right) = E_{\mathbf{\Psi}^{(0)}}\{\log\ L_c(\mathbf{\Psi})|\mathbf{y}\}$$

where the expectation operator E has the subscript $\mathbf{\Psi}^{(0)}$ to explicitly convey that this (conditional) expectation is being effected using $\mathbf{\Psi}^{(0)}$ for $\mathbf{\Psi}$.

The M-step requires the maximization of $Q(\mathbf{\Psi}; \mathbf{\Psi}^{(0)})$ with respect to $\mathbf{\Psi}$ over the parameter space $\mathbf{\Omega}$. That is, we choose $\mathbf{\Psi}^{(1)}$ such that

$$Q\left(\mathbf{\Psi}^{(1)}; \mathbf{\Psi}^{(0)}\right) \geq Q\left(\mathbf{\Psi}; \mathbf{\Psi}^{(0)}\right)$$

for all $\mathbf{\Psi} \in \mathbf{\Omega}$. The E- and M-steps are then carried out again, but this time with $\mathbf{\Psi}^{(0)}$ replaced by the current fit $\mathbf{\Psi}^{(1)}$. On the $(k+1)$ th iteration, the E- and M-steps are defined as follows:

- E-Step. Calculate $Q(\mathbf{\Psi}; \mathbf{\Psi}^{(k)})$, where

$$Q\left(\mathbf{\Psi}; \mathbf{\Psi}^{(k)}\right) = E_{\mathbf{\Psi}^{(k)}}\{\log L_c(\mathbf{\Psi})|\mathbf{y}\} \qquad [2]$$

- M-Step. Choose $\mathbf{\Psi}^{(k+1)}$ to be any value of $\mathbf{\Psi} \in \mathbf{\Omega}$ that maximizes $Q(\mathbf{\Psi}; \mathbf{\Psi}^{(k)})$; that is,

$$Q\left(\mathbf{\Psi}^{(k+1)}; \mathbf{\Psi}^{(k)}\right) \geq Q\left(\mathbf{\Psi}; \mathbf{\Psi}^{(k)}\right) \qquad [3]$$

for all $\mathbf{\Psi} \in \mathbf{\Omega}$.

The E- and M-steps are alternated repeatedly until the difference

$$L\left(\mathbf{\Psi}^{(k+1)}\right) - L\left(\mathbf{\Psi}^{(k)}\right)$$

changes by an arbitrarily small amount in the case of convergence of the sequence of likelihood values $\{L(\mathbf{\Psi}^{(k)})\}$. DLR showed that the (incomplete-data) likelihood function $L(\mathbf{\Psi})$ is not decreased after an EM iteration; that is,

$$L\left(\mathbf{\Psi}^{(k+1)}\right) \geq L\left(\mathbf{\Psi}^{(k)}\right) \qquad [4]$$

for $k = 0,1,2,\ldots$. Hence convergence must be obtained with a sequence of likelihood values that are bounded above.

It can be seen from the above that it is not necessary to specify the exact mapping from $\mathcal{X}$ to $\mathcal{Y}$, nor the corresponding representation of the incomplete-data density g in terms of the complete-data density g_c. All that is necessary is the specification of the complete-data vector $\mathbf{x}$ and the conditional density of $\mathbf{X}$ given the observed data vector $\mathbf{y}$. The choice of the complete-data vector $\mathbf{x}$ is not unique. It is chosen for computational convenience with respect to carrying out the E- and M-steps. The EM algorithm is really a generic device. As pointed out by a referee of the DLR paper, the use of the word 'algorithm' to describe this procedure can be criticized, "because it does not specify the sequence of steps actually required to carry out a single E- or M-step."

DLR established important fundamental properties of the EM algorithm. In particular, these properties imply that typically in practice the sequence of EM iterates will converge to a local maximizer of the log likelihood function $\log L(\mathbf{\Psi})$. If $L(\mathbf{\Psi})$ is unimodal in $\mathbf{\Omega}$ with $\mathbf{\Psi}^*$ being the only stationary point of $L(\mathbf{\Psi})$, then for any EM sequence $\{\mathbf{\Psi}^{(k)}\}$, $\mathbf{\Psi}^{(k)}$ converges to the unique maximizer $\mathbf{\Psi}^*$ of $L(\mathbf{\Psi})$. In general, if $\log L(\mathbf{\Psi})$ has several (local or global) maxima and stationary values, convergence of the EM sequence to either type depends on the choice of starting point. Furthermore, DLR shows that convergence is linear with the rate of convergence proportional to $\lambda_{\max}$, where $\lambda_{\max}$ is the maximal fraction of missing information. This implies that the EM algorithm can be very slow to converge, but then the intermediate values do provide very valuable statistical information. This also implies that the choice of the complete-data problem can influence the rate of convergence, since this choice will determine $\lambda_{\max}$; see the example given in Meng (1997) using the data of McKendrick (1926).

There have been quite a few developments in the methodology of the EM algorithm since DLR. In particular, Wu (1983) has given a detailed account of the convergence properties of the EM algorithm, addressing, in particular, the problem that the convergence of $L(\mathbf{\Psi}^{(k)})$ to L^* does not automatically imply the convergence of $\mathbf{\Psi}^{(k)}$ to a point $\mathbf{\Psi}^*$.

Often in practice, the solution to the M-step exists in closed form. In those instances where it does not, it may not be feasible to attempt to find the value of $\mathbf{\Psi}$ that globally maximizes the function $Q(\mathbf{\Psi}; \mathbf{\Psi}^{(k)})$. For such situations, DLR defined a generalized EM algorithm (GEM algorithm) for which the M-step requires $\mathbf{\Psi}^{(k+1)}$ to be chosen such that

$$Q\left(\mathbf{\Psi}^{(k+1)}; \mathbf{\Psi}^{(k)}\right) \geq Q\left(\mathbf{\Psi}^{(k)}; \mathbf{\Psi}^{(k)}\right) \qquad [5]$$

holds. The above condition on $\mathbf{\Psi}^{(k+1)}$ is sufficient to ensure that

$$L\left(\mathbf{\Psi}^{(k+1)}\right) \geq L\left(\mathbf{\Psi}^{(k)}\right)$$

Hence the likelihood $L\ (\mathbf{\Psi})$ is not decreased after a GEM iteration, and so a GEM sequence of likelihood values must converge if bounded above; see McLachlan and Krishnan (2008) for a discussion on what specifications are needed on the process of increasing the Q-function in order to ensure that the limit of $\{L\ (\mathbf{\Psi}^{(k)}\}$ is a stationary value and that the sequence of GEM iterates $\{\mathbf{\Psi}^{(k)}\}$ converges to a stationary point.

Example: Estimation of Mixing Proportions

The publication of the DLR paper greatly stimulated interest in the use of finite mixture distributions to model heterogeneous data. This is because the fitting of mixture models by ML is a classic example of a problem that is simplified considerably by the EM's conceptual unification of ML estimation from data that can be viewed as being incomplete. We consider here as an illustrative example the ML estimation of the proportions in which the components of the mixture occur, where the component densities are completely specified.

Suppose that the p.d.f. of a random vector W has a g-component mixture form

$$\left(f(\boldsymbol{w};\mathbf{\Psi}) = \sum_{i=1}^{g} \pi_i f_i(\boldsymbol{w}),\right) \qquad [6]$$

where $\mathbf{\Psi} = (\pi_1, \ldots, \pi_{g-1})^T$ is the vector containing the unknown parameters, namely the $g-1$ mixing proportions $\pi_1, \ldots, \pi_{g-1}$, since

$$\pi_g = 1 - \sum_{i=1}^{g-1} \pi_i$$

The component p.d.f.'s $f_i\ (\boldsymbol{w})$ are completely specified.

This mixture model covers situations where the underlying population is modeled as consisting of g distinct groups $G_1,\ldots,G_g$ in some unknown proportions $\pi_1, \ldots, \pi_g$, and where the conditional p.d.f of W given membership of the ith group G_i is $f_i\ (\boldsymbol{w})$. We let

$$\boldsymbol{y} = (\boldsymbol{w}_1, \ldots, \boldsymbol{w}_n)^T$$

denote the observed random sample obtained from the mixture density [6].

The log likelihood function for $\mathbf{\Psi}$ that can be formed from the observed data $\boldsymbol{y}$ is given by

$$\begin{aligned}\log\ L(\mathbf{\Psi}) &= \sum_{j=1}^{n} \log\ f(\boldsymbol{w}_j;\mathbf{\Psi}) \\ &= \sum_{j=1}^{n} \log\ \left\{\sum_{i=1}^{g} \pi_i f_i(\boldsymbol{w}_j)\right\}\end{aligned} \qquad [7]$$

On differentiating [7] with respect to π_i $(i = 1, \ldots, g-1)$ and equating the result to zero, we obtain

$$\sum_{j=1}^{n}\left\{\frac{f_i(\boldsymbol{w}_j)}{f(\boldsymbol{w}_j;\widehat{\mathbf{\Psi}})} - \frac{f_g(\boldsymbol{w}_j)}{f(\boldsymbol{w}_j;\widehat{\mathbf{\Psi}})}\right\} = 0 \quad (i = 1, \ldots, g-1) \qquad [8]$$

as the likelihood equation, which clearly does not yield an explicit solution for

$$\widehat{\mathbf{\Psi}} = \left(\widehat{\pi}_1, \ldots, \widehat{\pi}_{g-1}\right)^T$$

In order to pose this problem as an incomplete-data one, we now introduce as the unobservable or missing data the vector

$$\mathbf{z} = \left(\mathbf{z}_1^T, \ldots, \mathbf{z}_n^T\right)^T \qquad [9]$$

where $\mathbf{z}_j$ is a g-dimensional vector of zero-one indicator variables and where $z_{ij} = (\mathbf{z}_j)_i$ is one or zero according as whether $\boldsymbol{w}_j$ arose or did not arise from the ith component of the mixture $(i = 1, \ldots, g;\ j = 1, \ldots, n)$. Of course in some applications, the components of the mixture correspond to externally existing groups and so each realization $\boldsymbol{w}_j$ in the observed random sample from the mixture density does have a tangible component membership. But in other applications, component membership of the realizations is just a conceptual device to formulate the problem within the EM framework.

If these z_{ij} were observable, then the MLE of π_i is simply given by

$$\sum_{j=1}^{n} z_{ij}/n \quad (i = 1, \ldots, g) \qquad [10]$$

which is the proportion of the sample having arisen from the ith component of the mixture.

The EM algorithm handles the addition of the unobservable data to the problem by working with the current conditional expectation of the complete-data log likelihood given the observed data. On defining the complete-data vector $\mathbf{x}$ as

$$x = \left(y^T, z^T\right)^T \qquad [11]$$

the complete-data log likelihood for $\mathbf{\Psi}$ has the multinomial form

$$\log\ L_c(\mathbf{\Psi}) = \sum_{i=1}^{g}\sum_{j=1}^{n} z_{ij} \log \pi_i + C \qquad [12]$$

where

$$C = \sum_{i=1}^{g}\sum_{j=1}^{n} z_{ij} \log\ f_i(w_j)$$

does not depend on $\mathbf{\Psi}$.

As [12] is linear in the unobservable data z_{ij}, the E-step (on the $(k+1)$th iteration) simply requires the calculation of the current conditional expectation of Z_{ij} given the observed data $\boldsymbol{y}$, where Z_{ij} is the random variable corresponding to z_{ij}. Now

$$\begin{aligned}E_{\mathbf{\Psi}^{(k)}}\left(Z_{ij}|y\right) &= \mathrm{pr}_{\mathbf{\Psi}^{(k)}}\left\{Z_{ij} = 1|y\right\} \\ &= z_{ij}^{(k)}\end{aligned} \qquad [13]$$

where by Bayes' Theorem,

$$z_{ij}^{(k)} = \tau_i\left(w_j;\mathbf{\Psi}^{(k)}\right) \qquad [14]$$

and

$$\tau_i\left(w_j; \Psi^{(k)}\right) = \pi_i^{(k)} f_i(w_j)/f\left(w_j; \Psi^{(k)}\right) \quad [15]$$

for $i = 1,\ldots,g$; $j = 1,\ldots,n$. The quantity $\tau_i\ (w_j; \Psi)$ is the posterior probability that the jth member of the sample with observed value w_j belongs to the ith component of the mixture.

The M-step on the $(k+1)$th iteration simply requires replacing each z_{ij} by $z_{ij}^{(k)}$ in [10] to give

$$\pi_i^{(k+1)} = \sum_{j=1}^{n} z_{ij}^{(k)}/n \quad [16]$$

for $i = 1,\ldots,g$. Thus in forming the estimate of π_i on the $(k+1)$th iteration, there is a contribution from each observation w_j equal to its (currently assessed) posterior probability of membership of the ith component of the mixture model. This EM solution therefore has an intuitively appealing interpretation.

The computation of the MLE of π_i by direct maximization of the incomplete-data log likelihood function [7] requires solving the likelihood equation [8]. The latter can be identified with the iterative solution [16] provided by the EM algorithm after some manipulation (McLachlan and Krishnan, 2008).

Even before the formulation of the EM algorithm by DLR, various researchers have carried out these manipulations in their efforts to solve the likelihood equation for mixture models with specific component densities; see, for example, Day (1969). As demonstrated above for the estimation of the mixing proportions, the application of the EM algorithm to the mixture problem automatically reveals the iterative scheme to be followed for the computation of the MLE. Furthermore, it ensures that the likelihood values increase monotonically. Prior to the DLR paper, various researchers did note the monotone convergence of the likelihood sequences produced in their particular applications, but were only able to speculate on this monotonicity holding in general. As the $z_{ij}^{(k)}$ are probabilities, the E-step of the EM algorithm effectively imputes fractional values for the unobservable zero-one indicator variables z_{ij}. In so doing it avoids the biases associated with ad hoc iterative procedures that impute only zero-one values; that is, that insist on outright component membership for each observation at each stage rather than fractional allocation as with the EM algorithm.

Some Advances since DLR

One initial criticism of the EM algorithm was that it does not automatically provide an estimate of the standard errors, or the full covariance matrix in multivariate situations, of the MLE, as do some other approaches such as Newton-type methods. Hence since DLR, a number of methods have been proposed for assessing the covariance matrix of the MLE $\widehat{\Psi}$ of the parameter vector Ψ, obtained via the EM algorithm (McLachlan and Krishnan, 2008, Chapter 4). The other common criticism that has been leveled at the EM algorithm is that its convergence can be quite slow. Thus proposals have been put forward for accelerating its convergence (McLachlan and Krishnan, 2008, Chapter 5).

One of the major reasons for the popularity of the EM algorithm is that the M-step involves only complete-data ML estimation, which is often computationally simple. But if the complete-data ML estimation is rather complicated, then the EM algorithm is less attractive because the M-step is computationally unattractive. In many cases, however, complete-data ML estimation is relatively simple if maximization is undertaken conditional on some of the parameters (or some functions of the parameters). An account of such approaches can be found in McLachlan and Krishnan (2008). For instance, Meng and Rubin (1993) introduced a class of generalized EM algorithms, which they call the Expectation–Conditional Maximization (ECM) algorithm. The ECM algorithm takes advantage of the simplicity of complete-data conditional maximization by replacing a complicated M-step of the EM algorithm with several computationally simpler CM-steps. Each of these CM-steps maximizes the expected complete-data log likelihood function found in the preceding E-step subject to constraints on Ψ, where the collection of all constraints is such that the maximization is over the full parameter space of Ψ.

There are also the variants of the EM and ECM algorithms known as the Expectation–Conditional Maximization Either algorithm, the Alternating ECM algorithm, and the Parameter-Expanded EM algorithm aimed at speeding up convergence. These modified and extended versions all share the simplicity and stability of the EM and ECM algorithms.

There is now a whole battery of EM-related algorithms and more are still being developed. The current developments are, however, in the direction of iterative simulation techniques or MCMC methods, many of which can be looked upon as simulation-based versions of various EM-type algorithms.

Abstract

Computational approaches to model evaluation utilize the latest innovations in statistical computing to explore complex relationships between models and data. A wide variety of approaches have been proposed, all of which are intended to help researchers to select among competing explanations of a phenomenon under investigation. This article reviews several of these approaches, with an emphasis on their theoretical foundations, ranges of applicability, and timing of application in the scientific process.

Introduction

Rapid improvements in statistical computing technology over the last few decades have helped to fuel an explosion of interest in mathematical modeling in the social and behavioral sciences. As a result, 'modeling is now sufficiently mainstream that one can get the impression that models themselves are replacing the theories from which they evolved' (Pitt and Myung, 2002: p. 421). But a model is not interchangeable with a theory; it is merely one of many possible quantitative instantiations of a theory. Therefore it is possible to have several different models of the same phenomenon under investigation, each having justifiable assumptions, and each providing an adequate fit to the available data. In such cases, it is essential to have robust methods for evaluating and selecting among the competing models.

A thorough evaluation of a model requires a method that is sensitive to its overall data-fitting capabilities, not just its ability to fit a single set of data. The preferred approach to model evaluation is therefore to assess how well a model's fit to one data sample generalizes to future data generated by that same process (Myung, 2000). However, because a model's generalizability is not directly observable, this can be a difficult standard to implement in practice. Several different methods have been developed, varying in both their theoretical frameworks and ranges of applicability. This article reviews several of those methods, including minimum description length (MDL), Bayesian model selection, accumulative prediction error (APE), and parameter space partitioning (PSP).

A common thread in the various methods for evaluating generalizability is that they are applied after data have already been collected. In that sense, they are limited by the quality of the data that they have to work with. Therefore, their efficacy can be improved by making effective decisions prior to data collection, to ensure that the data will be maximally informative about the models under consideration. This article reviews two analyses that can aid in making such decisions: design optimization (DO) and adaptive design optimization (ADO).

What Makes a Model 'Good'

The first challenge in model evaluation is deciding what makes a model 'good.' On the face of it, the ability of a model to fit data generated in an experiment might seem like the only necessary criterion for model evaluation. Indeed, measures of fit such as root-mean-squares-error and percent-variance-accounted-for (r^2) are frequently reported in empirical research, and can often be computed at the touch of a button, thanks to modern software packages. However, such measures are not reliable for selecting among models because of the fact that data are not error-free. Rather, data are presumed to contain both inherent regularity and idiosyncratic noise: regularity reflecting the phenomenon of interest and noise resulting from measurement error and sampling error. The goal of modeling is to capture only the regularity, not the noise, but goodness-of-fit cannot distinguish between the two; it provides a single measure of a model's fit to both the regularity and the noise. Thus a model can achieve a good fit for the wrong reason by fitting noise instead of regularity. Therefore model selection based solely on a model's ability to fit a particular data sample may result in selecting a powerful model with little scientific significance.

Because it is impossible to eliminate error from data, additional criteria besides goodness-of-fit are required for evaluating models. One such criterion is 'model complexity,' which refers to the inherent flexibility in a model that enables it to fit diverse patterns of data. All other things being equal, simple models are attractive because they are sufficiently constrained to make them easily falsifiable. In contrast, a complex model does not assume a single structure in the data but, 'rather like a chameleon,' it is able to assume multiple structures by finely adjusting its parameter values (Myung and Pitt, 2009: p. 448). By virtue of this flexibility, a highly complex model can fit a data set better than a simple model can, even if the simpler model generated the data. It can do this by fitting both the regularity (good) and idiosyncratic noise (bad), whereas the simpler model would only fit the regularity. This problematic phenomenon is called 'overfitting' (Pitt and Myung, 2002).

What is desired for model evaluation is a yardstick that measures a model's ability to capture the underlying regularity only, not idiosyncratic noise. This is the *generalizability* criterion (Pitt et al., 2002). Generalizability refers to a model's ability to fit not only the current data sample, but also future data samples from the same data-generating process. A model generalizes best when it is just complex enough to fit the underlying regularity, but not so complex that it overfits the data. Thus, the challenge of maximizing generalizability can be

viewed as a delicate balancing act between goodness-of-fit and complexity (*see* Generalizability Theory).

Model Evaluation Statistics

Because a model's generalizability is not directly observable, it must be estimated based on an analysis of the relationship between the model and the observed data sample. This can be done by computing model selection statistics, which are powerful and principled tools for evaluating models. Several different model selection statistics have been developed, and although they may differ in their theoretical underpinnings, each one implements the generalizability criterion by trading off goodness-of-fit and model complexity. This section discusses three model selection statistics: MDL, Bayes factor, and APE.

Minimum Description Length

The MDL principle is a method of inference based on information theory. It proposes that the basic goal of modeling should be to formalize regularities in the data, and that the extent to which a model can compress the data indicates how well it achieves that goal (*see* Algorithmic Complexity). Thus the goal of model selection by MDL is to identify the model that allows the greatest compression of the data. Conceptually, the intent is not to discover the truth about the world so much as it is to provide the most concise account of our observations about the world. This section offers a brief introduction to the conceptual foundations of MDL and its implementation via the normalized maximum likelihood (NML). For full details, the reader is encouraged to refer to Grünwald (2007).

The key measure for model evaluation under the MDL approach is the 'code length' of the data under the model. The code length can be thought of as the number of symbols needed to represent the data by way of the model; a shorter code length means better compression of the data. This code length is approximated by way of the NML (Rissanen, 2001). The NML measures how well a model fits observed data, relative to how well that model could fit any possible data. Formally, the NML is given by

$$\mathrm{NML} = \frac{f\left(x|\widehat{\theta}_x\right)}{\int f\left(y|\widehat{\theta}_y\right)} \qquad [1]$$

where $\widehat{\theta}_x$ denotes the maximum likelihood estimate for the observed data set x, and $\widehat{\theta}_y$ denotes the maximum likelihood estimate for a hypothetical data set y. Thus the NML of the data set x is proportional to the maximized likelihood value, normalized by the sum of maximum likelihoods of all potential data sets that could be observed in an experiment. When x is defined over a discrete sample space (e.g., binomial data), the integration symbol is replaced by a summation symbol.

The code length of the NML is referred to as the 'stochastic complexity' of the data set x (with respect to the model M), and is given by

$$\mathrm{MDL} = -\ln f\left(x|\widehat{\theta}_x\right) + \ln \int f\left(y|\widehat{\theta}_y\right)\mathrm{d}y \qquad [2]$$

The first term in eqn [2] is a measure of the lack of fit of the model to the data. The second term is a measure of model complexity. Therefore, model evaluation by MDL is carried out by trading off lack of fit for complexity. The complexity term measures how well the model fits across all possible data sets and can be interpreted conceptually in the following way: a model that fits almost every data pattern very well would be much more complex than a model that provides a relatively good fit to a small set of data patterns but does poorly otherwise.

The integral in eqn [2] is over all possible data sets that could be observed in the same experiment that yielded x. In all but the simplest cases, this integral is computationally intractable (although, for an illustrative calculation with binomial data, see Shiffrin et al., 2008). Therefore, the stochastic complexity must be approximated. A useful approximation is given by

$$\mathrm{FIA} = -\ln f\left(y|\widehat{\theta}_y\right) + \frac{k}{2}\ln\left(\frac{n}{2\pi}\right) + \ln \int \sqrt{\det I(\theta)}\mathrm{d}\theta \qquad [3]$$

where n denotes the sample size, k is the number of model parameters, and det $I(\theta)$ is the determinant of the Fisher information matrix. This is known as the Fisher information approximation (FIA) (Rissanen, 1996).

Although eqn [3] is often much easier to evaluate than eqn [2], it is important to note that the FIA may exhibit anomalous behavior if certain conditions are not satisfied. Rissanen (1996) remarks that the most important things to verify are that the maximum likelihood estimate lies 'sufficiently inside' the interior of the model, that all elements of the Fisher information matrix are continuous in θ, and that the integral term is finite.

Bayesian Model Selection

A related model selection statistic to MDL can be derived from statistical theory. In Bayesian statistics, models are evaluated based on their posterior probabilities, given the observed data (those not familiar with Bayesian statistics should *see* Bayesian Statistics, Theory of). The ratio of the posterior probabilities of two models is known as the Bayes factor, and it measures the evidence that the data provides for one model over another (Kass and Raftery, 1995). Numerous computational methods have been developed for estimating the Bayes factor, mostly based on a computer-driven sampling methodology known as *Markov chain Monte Carlo* (MCMC). A recent summary lists as many as 15 different methods (Gamerman and Lopes, 2006, Chapter 7).

Although the Bayesian approach to model evaluation is derived from an entirely different theoretical framework than the MDL approach, the two approaches are closely connected in a number of ways. Like MDL, Bayesian model selection also maximizes generalizability by trading off goodness-of-fit and model complexity. This can be seen most clearly in the Bayesian information criterion (BIC), which was derived by Schwarz (1978) as an asymptotic approximation to the negative log of the posterior probability of a candidate model. The BIC is given by

$$\mathrm{BIC} = -2\ln f\left(y|\widehat{\theta}_y\right) + k\ln\left(\frac{n}{2\pi}\right) \qquad [4]$$

where, again, y is the observed data sample, $\widehat{\theta}_y$ is the maximum likelihood estimate for y, k is the number of parameters, and n is the sample size. The model with the lowest BIC is preferred. Just as in the expression for MDL in eqn [2], the first term in eqn [4] can be seen as a measure of lack of fit and the second term can be seen as a measure of model complexity.

A stronger connection between the Bayesian and MDL approaches to model evaluation can be seen by examining the FIA expression in eqn [3] and noting that the sample size appears in the second term but not the third. It follows that the contribution of the third term relative to that of the second term becomes negligible as the sample size becomes large. Neglecting the third term and multiplying the result by 2 yields the BIC. Yet another derivation of MDL as an asymptotic approximation of the Bayesian posterior probability can be obtained by assuming a special form of the parameter prior density (Myung et al., 2006). These connections between Bayesian model selection and MDL reveal that choosing the model that gives the shortest description of the data is essentially equivalent to choosing the model that is most likely to be true in the sense of probability theory.

The Prequential Approach

A third model selection statistic, also related to MDL and the Bayes factor, can be derived from a framework of predictive inference. The prequential approach (the name is derived from 'sequential prediction'; Dawid, 1984) is based on minimizing prediction error for unseen data. Conceptually, this is a direct implementation of the generalizability criterion in the sense that the model that generalizes best to future data should also have the smallest prediction errors for future data coming from the same source.

To see how this approach can be implemented in practice, consider a case in which data points are observed sequentially in an experiment. Suppose that after each data point is observed, a model is used to make a prediction about the next data point based on all of the data that have been observed so far in the experiment. The sum of the errors in those predictions is called the 'accumulative one-step-ahead prediction error' (APE; Wagenmakers et al., 2006) of the model. The lower the APE for a model, the better it is at predicting future data from past data.

The prequential approach has strong theoretical ties to both Bayesian- and MDL-based model selection. Wagenmakers et al. (2006) show that APE, when implemented with a logarithmic loss function and Bayesian one-step-ahead predictions, is equivalent to Bayesian model selection. They further show that, under many other conditions, APE, MDL, and Bayesian model selection converge as many data are collected. Consequently, the three different approaches to maximizing generalizability that have been presented: (1) choosing the model that is best at predicting future data from past data, (2) choosing the model that is most likely to be true in the sense of probability theory, and (3) choosing the model that provides the shortest description of the data – are essentially equivalent. For a discussion of the relative advantages and disadvantages of these three approaches, the reader is encouraged to refer to the review by Shiffrin et al. (2008).

Evaluation of Other Types of Models

Model selection statistics are valuable tools for evaluating models, but their usefulness is limited when confronted with the diverse range of models in the social and behavioral sciences. The primary limitation is that their application requires each of the models under consideration to be formulated as a parametric family of probability distributions. This leaves out many important classes of models such as connectionist models (*see* Cognitive Modeling: Connectionist Approaches), simulation-based models (*see* Social Simulation, Computational Approaches), and cognitive architectures (*see* Information-Processing Architectures: Fundamental Issues). Another limitation is that they summarize the potentially intricate relationship between model and data into a single real number, whereas researchers are often interested in a more nuanced analysis of the model–data relationship. For example, one might want to know what range of data patterns a model is capable of fitting, beyond that of the current data sample, and whether those patterns resemble human behavior. Overcoming these limitations requires a different approach to model evaluation. One such approach, called PSP, is described next. For a more thorough presentation of this material, including technical and implementation details of the method, the reader should refer to Pitt et al. (2006).

Parameter Space Partitioning

To understand PSP, it is useful to view models as data-generating mechanisms. In this view, a model can be said to be consistent with an empirical pattern of data if it can generate patterns of data that are qualitatively similar to the empirical pattern (i.e., it can fit the data) for some value of its parameters. However, evaluating a model's ability to reproduce a given pattern of data provides only a glimpse of what the model can do. In many cases, it would be useful to know what other qualitative patterns the model could produce. For example, if the model can produce any logically possible pattern of data, then its ability to reproduce the empirical pattern would be much less impressive. In that sense, there is a problem of qualitative model complexity in this type of evaluation.

PSP is sensitive to this qualitative notion of model complexity, and rather than quantifying it, PSP generates a map of the model's parameter space indicating which regions correspond to qualitatively distinct predictions. Study of this map provides insights into the global performance of the model and provides several criteria on which to compare models. For example, one could compare models by counting the number of distinct, qualitative patterns of data that each model can produce. Alternatively, if the empirical data can only be produced by a tiny region within a model's parameter space, one might consider it to be irrelevant to the model's overall performance and favor a model for which empirical data are more representative.

Implementation of PSP begins with defining what constitutes a data pattern. This definition will vary by situation depending on the pertinent characteristics of the models and data under study. What is important is that this definition discretizes the prediction space into a finite set of distinct patterns. Once a data pattern is defined, the next task

in applying PSP is to map the model's parameter space according to the data patterns that it can generate. A simple solution to this problem would be to evaluate or simulate the model on a fine grid of points spanning the parameter space and keep track of the pattern produced at each point. However, for every parameter in the model, the search space increases by one dimension. Even with as few as six parameters, brute-force search methods such as grid search are too inefficient to finish in a reasonable amount of time. For example, if a model has six parameters, each of which can range from zero to one, and one wished to search the full parameter space by means of a grid of points spaced at increments of 0.01, then one trillion (100^6) sample points would need to be evaluated.

To facilitate the mapping of higher dimensional parameter spaces, Pitt et al. (2006) proposed an MCMC-based search algorithm. The idea of the algorithm is to build chains of parameter points corresponding to the same pattern. The algorithm starts at a single point, and spawns new chains as new patterns are found. The theory of MCMC guarantees that each chain generated through this process will be uniformly distributed over the region of the parameter space corresponding to the same data pattern. The volumes of these regions can then be estimated by multidimensional ellipsoids using the estimated mean and covariance matrix of the MCMC sample of the region. A Java illustration of the algorithm, and Matlab code for its implementation, are available at the PSP homepage on J. I. Myung's website.

Model Evaluation at the Front End of an Experiment

Model selection tools assist researchers in making inferences about models given data samples collected in experiments. However, because they are applied after data have been collected, their potential to yield definitive conclusions is limited by the quality of the empirical data that they have to work with; sometimes the data simply do not provide a clear differentiation between models. The problem is that although models aim to predict patterns of data across a wide range of possible stimuli, practical limitations force researchers to select only a handful of them for actual testing. If the selected stimuli do not permit a clear differentiation of model predictions, then model selection may be inconclusive. Therefore, the choice of stimuli is critical.

The choice of stimuli is just one aspect of experimental design that can affect the potential informativeness of the result. Other design parameters such as the sample size, the number of treatments, and the proportion of observations to be allotted to each treatment group must be chosen. These choices impact not only the statistical value of the results but also the cost of the experiment. In that sense, an optimal design is one that maximizes the informativeness of the experiment while being cost-effective for the experimenter. This section discusses computational approaches to finding optimal designs. For more details, the reader is encouraged to see the recent articles by Myung and Pitt (2009) and Cavagnaro et al. (2010), from which the material in this section is primarily drawn.

Design Optimization

DO applies statistical inference at the front end of the experiment (before data have been collected) in order to make model evaluation easer at the back end of the experiment (after data have been collected). Statistical inference is used to exploit design variables (e.g., treatment levels and values, presentation schedule) with the aim of identifying an optimal experimental design that will produce the most informative data. It is similar to a power analysis that is conducted in the planning stages of an experiment, but instead of identifying only the optimal number of participants to test, the optimal experimental design as a whole is identified.

The basic idea behind DO is as follows. To identify an optimal design, one must be able to define the design space, which refers to all possible designs that could be used in an experiment. In addition, the model being evaluated must be expressed in formal, mathematical terms, with a parametric likelihood function. An optimal design is chosen according to a Bayesian, decision-theoretic framework in which each possible experimental design is treated as a gamble, whose payoff is determined by the outcome of an experiment carried out with that design. The idea is to estimate the informativeness of hypothetical experiments carried out with a given design, so that an 'expected utility' of that design can be computed. This is done by considering every possible observation that could be obtained from an experiment with that design and then evaluating the relative likelihoods and utilities of those observations. The design with the highest expected utility is chosen as the optimal design. Formally, the expected utility of a design is given by

$$U(d) = \sum_{m=1}^{K} p(m) \iint u(d, \theta_m, y) p(y|\theta_m, d) p(\theta_m) \mathrm{d}y \mathrm{d}\theta_m \qquad [5]$$

where $m = 1, \ldots, K$ is a set of K models being considered, d is a design, y is the outcome of an experiment with design d under model m, and θ_m is a parameterization of model m. The function $u(d, \theta_m, y)$ inside the integral in the above equation is called the 'local utility' of the design d. It measures the utility of a hypothetical experiment carried out with design d when the true model is m with parameter value equal to θ_m and the outcome y is observed. Thus, the global utility function $U(d)$ represents the expected value of the local utility function, where the expectation is taken over prior distributions on models, $p(m)$, and model parameters, $p(\theta_m)$, and all possible observations given a particular model-parameter pair through the sampling distribution $p(y|\theta_m, d)$.

Selection of a local utility function that captures the goals of the experiment is critical to the success of DO. For example, if the goal of the experiment is to discriminate among models, then the local utility function should measure the extent to which the models are discriminated by the hypothetical experiment, through a measure such as model recovery rate or posterior model probability. See Myung and Pitt (2009) for more details.

Adaptive Design Optimization

Application of DO does not have to be a one-shot process performed prior to an experiment. The decision-theoretic

framework of DO can easily be extended to apply adaptively throughout the course of an experiment. In an adaptively designed experiment, testing proceeds over the course of multiple stages, each of which may have a different design. At each stage, the information gained from all preceding stages is used to improve the design at the current stage. Thus the problem to be solved in ADO is to identify the most informative design at each stage of the experiment, taking into account the results of all previous stages, so that one can infer the underlying model and its parameter values in as few steps as possible. This is done by applying eqn [5] after each stage, with the prior distributions $p(m)$ and $p(\theta_m)$ replaced by posterior distributions $p(m|D)$ and $p(\theta_m|D)$, obtained through Bayesian updating (Gelman et al., 2004) based on the data D that have been collected so far in the experiment. For additional details, see Cavagnaro et al. (2010). C++ code is available on J. I. Myung's website.

Conclusions

Investigating the relationship between models and data is at the heart of the scientific endeavor. Our ability to model complex phenomena has increased substantially in recent decades, thanks in part to technological innovations in scientific computing. Although an abundance of models is a sign of a productive area of research, it also increases the importance of having robust methods for evaluating and selecting among models. Fortunately, the same technological innovations have also facilitated the development of sophisticated model evaluation methods. These methods differ in their theoretical foundations, in their ranges of applicability, and in the timing of their application (before or after data collection), but they are united in their aim to enhance our understanding of the complex relationship between models and data.

Abstract

The goal of computational neuroscience is to understand how brains generate behaviors using computational approaches. Computational models of the brain explore how populations of highly interconnected neurons are formed during development and how they represent, process, store, act upon, and become altered by information present in the body and the environment. Techniques from physics, computer science, and mathematics are used to simulate and analyze these computational models and provide links between the wide range of levels that brains are investigated, from molecular interactions to large-scale systems. Models are also used for interpreting experimental data and providing a conceptual framework for the dynamical properties of neural systems, which should lead to more comprehensive theories of brain function.

Many different types of physical systems can solve computational problems, including slide rules and optical analog analyzers as well as digital computers, which are analog at the level of transistors and must settle into a stable state on each clock cycle. What these have in common is an underlying correspondence between an abstract computational description of a problem, an algorithm that can solve it, and the states of the physical system that implement it. This is a broader approach to computation than one that is based purely on symbol processing (Marr, 1982; Schwartz, 1990; Churchland and Sejnowski, 1992; Dayan and Abbott, 2001; Arbib, et al., 2002; Eliasmith and Anderson, 2003; Sterratt et al., 2011). (Figures 1 and 2).

There is an important distinction between general-purpose computers, which can be programmed to solve many different types of algorithms, and special purpose computers, which are designed to solve only a limited range of problems. Most neural systems are specialized for particular tasks, such as the retina, which is dedicated to visual transduction and image processing. As a consequence of the close coupling between structure and function, the anatomy and physiology of a brain

Figure 1 Multiscale levels of investigation for studying the brain. Each level requires a different type of model to explain the dynamical interactions between structures over a wide range of timescales. Integration across levels occurs by mapping the details of a lower level model into the parameters of a model at a higher level. Adapted from Churchland, P.S., Sejnowski T.J., 1992. The Computational Brain. MIT Press, Cambridge, MA.

Figure 2 Levels of analysis. The computational level defines the problem to be solved; the algorithmic level provides procedures for solving the problem; the implementation level has devices that instantiate the algorithms. The two-way arrows indicate that constraints between levels can be used to gain insights in both directions. Theoretical approaches often start at the computational level and proceed downward toward the implementation level. Research in computational neuroscience often starts at the implementation level and proceeds up to the computational level. Adapted from Marr, D., 1982. Vision. Freeman, New York.

area can provide important clues to the algorithms that it implements and its computational function; in contrast, the hardware of a general-purpose computer may not reveal its function, which also depends on what software it is running.

Another major difference between brains and general-purpose digital computers is that computers are hardwired, but the connectivity between neurons and their properties are shaped by the environment during development and remain plastic even in adulthood. Thus, as the brain processes information, it changes its own structure in response to the information that is being processed. Adaptation and learning are important mechanisms that allow brains to respond flexibly as the world changes on a wide range of timescales, from milliseconds to years. The flexibility of the brain has survival advantage when the environment is nonstationary and the evolution of some cognitive skills may deeply depend on genetic processes that have extended the timescales for brain plasticity.

Brains are complex, nonlinear dynamical systems with feedback loops, and brain models provide intuition about the possible behaviors of such systems. The predictions of a model make explicit the consequences of the underlying assumptions, and comparison with experimental results can lead to new insights and discoveries. Emergent properties of neural systems, such as oscillatory behaviors, depend on both the intrinsic properties of the neurons and the pattern of connectivity between them. For example, the large-scale coherent brain rhythms that accompany different states of alertness and sleep arise from intrinsic properties of thalamic and cortical neurons that are reciprocally connected (Destexhe and Sejnowski, 2001).

Models at Different Levels of Detail

Realistic Models

Perhaps the most successful model at the level of the neuron has been the classic Hodgkin–Huxley model of the action potential in the giant axon of the squid (Koch, 1999; Koch and Segev, 2003). Data were first collected under a variety of conditions, and a model was later constructed to integrate the data into a unified framework. This type of model requires that most of the parameters in the model have been measured experimentally and only a few unknown parameters need to be fit to the data. Detailed models can be used to distinguish between different explanations of the data. Realistic models of thousands of interacting neurons can be explored with computer simulations.

In realistic models of neuron, synaptic signals are integrated on dendrites, leading to action potentials that are initiated near the soma and carried to other neurons through long axons. In compartmental models of neurons, dendrites and axons are modeled as cables with voltage-dependent ion channels, ligand-gate receptors, and ion transporters (Stuart et al., 1999; De Schutter, 2009). The great diversity of ion channels found in different combinations in different types of neurons gives rise to a wide range of properties. More than one set of parameters can reproduce a particular set of electrical recordings, which emphasizes the need for additional constraints on realistic models (Prinz et al., 2004). Active currents allow nonlinear integration to take place in dendritic branches and can support backpropagating action potentials that carry information in a retrograde direction from the cell body back to the distal synapses tree and influence synaptic plasticity through mechanisms that discussed below in the Section Learning and Memory.

The first model for the orientation specificity of neurons in the visual cortex was the feedforward model proposed by Hubel and Wiesel, which assumed that the orientation preference of cortical cells was determined primarily by converging inputs from thalamic relay neurons. Although there is strong experimental evidence for this model, local cortical circuits have been shown to be important in amplifying weak signals and suppressing noise as well as performing gain control through inhibitory feedback to normalize responses and extend the dynamic range. Models of competition between neurons in cortical circuits can explain many properties of single cortical neurons in awake, behaving monkeys during attention tasks (Reynolds and Heeger, 2009). These cortical models are governed by the type of attractor dynamics that was analyzed by John Hopfield (1982), who provided a conceptual framework for the dynamics of feedback networks.

Although the spike trains of cortical neurons are highly irregular, and are typically treated statistically, information may be contained in the timing of the spikes in addition to the average firing rate. This is well established for a variety of sensory systems in invertebrates and peripheral sensory systems in mammals (Rieke et al., 1996), but whether spike timing carries information in cortical neurons is an open research issue. In addition to representing information, spike timing could also be used to control synaptic plasticity through Hebbian mechanisms for synaptic plasticity, as discussed below in the Section Learning and Memory.

Small neural systems have been analyzed with dynamical systems theory (Izhikevich, 2006; Gerhard et al., 2013). This approach is feasible when the numbers of parameters and variables are small. Most models of neural systems involve a large number of variables, such as membrane potentials, firing rates, and concentrations of ions, with an even greater number of unknown parameters such as synaptic strengths, rate constants, and ionic conductances. In the limit that the number of neurons and parameters is very large, techniques from statistical physics become applicable in predicting the average behavior of large systems (van Vreeswijk and Sompolinsky, 1998). There is a midrange of system sizes where neither type of limiting analysis is possible, but where simulations can be performed (Bower and Beeman, 2007). One danger of relying solely on computer simulations is that they may be as complex and difficult to interpret as the biological system itself.

Signal Processing Models

Other types of models have been used to analyze experimental data in order to determine whether they are consistent with a particular computational assumption. For example, a 'vector averaging' technique has been used to compute the direction of arm motion from the responses of cortical neurons (Georgopoulos et al., 1986) and signal detection theory was used to analyze the information from cortical neurons responding to visual motion stimuli (Movshon and Newsome,

1996). The spatial tuning curves for neurons in the motor cortex could also be used to solve the equations of motion for multijoint arm movements (Tanaka and Sejnowski, 2013). Bayesian methods can effectively decode the position of a rat in a maze from place cell recorded in the hippocampus (Zhang et al., 1998). In these examples, the computational model was used to explore the information in the data but was not meant to be a model for the actual cortical mechanisms. Nonetheless, these models have been highly influential and have provided new ideas for how populations of neurons may represent sensory information and motor commands.

Cognitive Models

It is becoming possible to begin simulating cognitive functions such as perceiving, attending, deciding, and moving as computing continues to expand (van Hemmen and Sejnowski, 2006; Eliasmith et al., 2012). Neural network models that simplify the intrinsic properties of neurons can be helpful in understanding the computational consequences of information contained in large populations of neurons. An example of this approach is model of parietal cortex based on the response properties of cortical neurons (Pouget and Sejnowski, 2001). The parietal cortex is involved in representing spatial location of objects in the environment and computing transformations from sensory to motor coordinates. The model examined the issue of which reference frames are used in the cortex for performing these transformations. The model predicted the outcomes of experiments performed on patients with spatial neglect following lesions of the parietal cortex.

The oculomotor system has had a long tradition of using control theory models to guide experimental studies. Large-scale models of vertebrate brains are also becoming possible, especially in highly organized structures such as the retina, cerebellum, and cerebral cortex. However, despite the relatively stereotyped anatomical structure of the cerebellum, we still do not understand its computational functions. Early theories of the cerebellum as a motor controller have to be modified based on functional imaging studies that suggest that the cerebellum is also involved in higher cognitive functions. Modeling studies may help in exploring competing hypotheses.

Learning and Memory

One of the goals of computational neuroscience is to understand how long-term memories are formed through experience and learning. The strengths of interactions between neurons can be altered by activity. For example, high-frequency trains of stimuli at synapses in the hippocampus induce a form of long-term potentiation (LTP) that can last for days (Cooke and Bliss, 2006). Moreover, these synapses require simultaneous presynaptic activity and postsynaptic depolarization, as suggested by Hebb (1949). Hebbian synaptic plasticity can also be used to form maps and has been used to model the early development of the projection from the thalamus to the visual cortex (Toyoizumi and Miller, 2009). In particular, these models can explain why inputs from the right and left eyes form alternating stripes in primary visual cortex of cats and monkeys called ocular dominance columns. Specific mappings arise in the cortex because temporal contiguity in axonal firing is translated into spatial contiguity of synaptic contacts.

The change in the strength of synapses in the hippocampus and neocortex depends on the relative timing of spikes in the presynaptic neuron and the postsynaptic neuron. Reliable LTP occurs when the presynaptic stimulus precedes the postsynaptic spike, but there is long-term depression (LTD) when the presynaptic stimulus immediately follows the postsynaptic spike (Feldman, 2012). This temporally asymmetry in synaptic plasticity solves the problem of balancing LTD and LTP since chance coincidences should occur about equally with positive and negative relative time delays. When sequences of inputs are repeated in a network of neurons with recurrent excitatory connections, temporally asymmetric synaptic plasticity will learn the sequence and the pattern of activity in the network will tend to predict future inputs. There is evidence for this in the hippocampus where place cells representing nearby locations in a maze may be linked together (Blum and Abbott, 1996) and in visual cortex where simulations of cortical neurons can become directionally selective when exposed to moving visual stimuli (Shon et al., 2004).

The temporally asymmetric Hebbian learning rule can be used to implement the temporal difference learning algorithm in reinforcement learning and classical conditioning (Montague and Sejnowski, 1994; Sutton and Barto, 1998; Rao and Sejnowski, 2001). The unconditioned stimulus in a classical conditioning experiment must occur before the reward for the stimulus–reward association to occur. This is reflected in the temporal difference learning algorithm by a postsynaptic term that depends on the time derivative of the postsynaptic activity level. The goal is for the synaptic input to predict future reward: if the reward is greater than predicted the postsynaptic neuron is depolarized and the synapse strengthens, but if the reward is less than predicted, the postsynaptic neuron is hyperpolarized and the synapse decreases in strength. There is evidence in primates that the transient output from dopamine neurons in the ventral tegmental area carry information about the reward predicted from a sensory stimulus (Schultz et al., 1997).

The temporal window for classical conditioning is several seconds, much longer than the window for LTP/LTD observed at cortical and hippocampal synapses. A circuit of neurons in the basal ganglia and frontal cortex may be needed to extend the computation of temporal differences to these long time intervals (Sejnowski et al., 2014). It is surprising to find the same learning algorithm in different types of learning systems in different parts of the brain. This suggests that the temporal order of input stimuli is a useful source of information about causal dependence in many different learning contexts and over a range of time scales.

Future Directions

Molecular/Synaptic

Almost all of the proteins that make up synapses are now known and they sequencing of the human genome will make it possible to complete that list within the next 5 years. Coupled with high-voltage electron microscopy and methods for labeling these proteins it should be possible to develop a reasonably complete model for the neuromuscular junction and central synapses

within the next decade. This will allow us to understand the synapses as a molecular machine and to understand the mechanisms that are involved in synaptic plasticity (O'Donnell and Sejnowski, 2014). It is highly likely that advances in modeling and computational theory at this level will have direct impact on the pharmaceutical industry through the design of new drugs and new approaches to mental disorders.

Neuron/Network

Progress in this area has been slower because experimental technique for recording from many neurons simultaneously still lags behind. However, the advent of large electrode arrays and optical recording and stimulation techniques (Fenno et al., 2011) and reconstruction methods for circuits from electron microscope images (Denk et al., 2012) have made possible rapid progress. Computer models are being used to understand how the intrinsic properties of neurons and the synapses that join them produce complex spatiotemporal patterns of activity and how these networks are used to encode, store, and retrieve information in large neural systems.

Map/System

Functional magnetic resonance imaging has made it possible to localize activity within the human brain. New approaches, such as diffusion tensor imaging of long-range fiber tracts and magnetic resonance spectroscopy, should make it possible to extend current techniques to explore other structural and functions aspects of the brain (Smith et al., 2013). However, until the time resolution of these new techniques is improved, or they can be integrated with other techniques such as electroencephalography and magnetoencephalography, it will not be possible to uncover the mechanisms that underlie the activity that is observed with functional imaging. Understanding of brains at this integrated level will provide the ultimate insights into major philosophical questions about consciousness and autonomy (Koch, 2004).

Technology for Brain Modeling

Do new properties emerge as the number of neurons in a neural system becomes large? This question can be explored with large simulations of millions of neurons. Parallel computers have become available that permit massively parallel simulations, but the difficulty of programming these computers has limited their usefulness. An approach to massively parallel models introduced by Carver Mead is based on subthreshold cMOS VLSI (complementary metal–oxide–semiconductor very large-scale Integrated) circuits with components that mimic the analog computational operations in neurons. Several large silicon chips have been built that mimic the visual processing found in retinas. Analog VLSI cochleas have also been built that can analyze sound in real time. Analog VLSI chips have been built that mimic the detailed biophysical properties of neurons, including dendritic processing and synaptic conductances. These chips use analog voltages and currents to represent the signals, and are extremely efficient in their use of power compared to digital VLSI chips. A new branch of engineering called *neuromorphic engineering* has arisen to exploit this technology (Liu et al., 2015).

Conclusions

Although brain models are now routinely used as tools for interpreting data and generating hypotheses, we are still a long way from having explanatory theories of brain function. Digital computers have been increasing in computing power and data storage exponentially since 1950 and have transformed how experiments are performed, data are analyzed and the development of brain models and theories. Advance in brain imaging techniques, which has made it possible to study human brain activity noninvasively, would not have been feasible without fast digital computers. Similarly, improvements in optical imaging have been made by counting photons and computationally reconstructing subcellular structure with unprecedented resolution. The increasing power of computers is transforming our ability to analyze complex neural systems at many levels of investigation and will have far-reaching consequences.

At this stage in our understanding of the brain, a model should only be considered a provisional framework for organizing thinking and designing new experiments. Many partial models need to be explored at many different levels of investigation (**Figure 1**), each model focusing on a different scientific question. As computers become faster, and as software tools become more flexible, computational models will become increasingly important for guiding research. Close collaborations between modelers and experimentalists, facilitated by the Internet, should lead to an increasingly better understanding of the brain as a computational system.

Computational Organizational Theory

Geoffrey P Morgan and Kathleen M Carley, Carnegie Mellon University, Pittsburgh, PA, USA

Published by Elsevier Ltd.

Abstract

Research in computational organizational theory explores the complex interactions between organizations and their members. Organizations are legally autonomous entities that structure the efforts of individuals to achieve large goals. Interesting behavior often emerges from the interactions and demands of modeled primitives. This introduction describes the common ground and recent advances in multimodeling, multilevel modeling, and rapid model development. We conclude this summary with discussion of issues of model fidelity and model validation.

Introduction

Computational organization theory (COT) is a research discipline, which develops formal computational models to understand, extend, and examine organizational theory. Specific questions of interest to researchers in this field include organizational decision making, adaptation, and organizational learning. Often, these researchers are interested in the complex interdependencies between individuals and the organizations of which they are members. Organizations need individuals to make decisions, yet individuals benefit from membership in an organization: the organization is not merely the sum of its members.

Models developed by COT researchers tend to embody theory, represented as mathematical and computational structures and processes, of how an organization may behave. These models are intended to reproduce behavior analogous to the behavior of real-world organizations, but are implemented as computer programs. These models can be created and tested through low-cost simulation methodologies – although validation usually requires some form of comparison with either empirical data or with another model, which has been compared to empirical data (e.g., see Schreiber and Carley, 2013).

Organizational models have been implemented in many diverse ways – most often in the way that best suited the theoretical premises of the modeler and with which the modeler was fluent. These methods vary from formal mathematical models to boundedly rational agent models. Organizational models tend to focus on either processes (where the people are implicit) or people (where the processes are often implicit). This article focuses on organizational models that place the individual as an organizational decision maker, a people-oriented perspective (although subgroups may also be represented in such models). Thus, these models are multiagent simulations.

There are other methods for modeling organizations. For a thorough introduction to the art of modeling organizations as collections of intertwined processes, see Carlsen (1997) or Jørgensen (2004). In contrast, some researchers are primarily interested in organizational ecologies (Hannan and Freeman, 1977) – where the primary unit of analysis are organizations, rather than people within those organizations. Recent work in multilevel modeling (discussed below) is attempting to unite these various perspectives.

This article will frequently draw examples and grounding by presenting ideas from Construct (Carley, 1991a; Carley et al., 2009). Construct is a turn-based network-centric simulation of information and belief diffusion, based on the theory of Constructuralism (Carley, 1991b), and inheriting the information processing perspective of the Carnegie School (Simon, 1957; Cyert and March 1963).

Computational models, instantiated as simulations, are valuable to researchers in multiple ways. Computational methods allow theoreticians to explore the sources of complex and interesting organizational behavior, often finding that relatively simple rules when localized and in aggregate can produce these phenomena. This idea, that the interactions of simple processes produce complex and interesting behavior, is often called *emergence*. These methods also allow theoreticians to explore how large classes of organizations may behave in a particular environment of interest compared to other organizations from the same classification scheme. In general, the translation of theory into computational model tends to require that theory to be expressed with more clarity and precision than that required by textual description, which improves the resulting descriptions of the theory.

For applied research, computational models allow researchers to explore counterfactual scenarios for specific organizations of interest. These counterfactual scenarios allow researchers to answer 'what-if' questions, which it would be impossible to explore practically or ethically in the real world. Model results, of course, cannot be assumed to provide a specific and valid prediction of outcomes, but can often (if the theoretical model has been validated) be useful to examine from a trend analysis perspective.

COT makes these important assumptions about organizations and phenomena:

- Phenomena are modelable. If we cannot model it, we cannot examine it.
- Uncertainty is important. Individuals make mistakes. Environmental conditions can rapidly shift.
- Humans are boundedly rational. Because of cognitive and physical limitations, humans do not know everything about the world they live in, what they know may be wrong, and they may not be able to access what they know at all times.
- Organizations are organized to do work. Most metrics focus, explicitly or implicitly, on task performance.

- Outcomes are path dependent. Choices made in the past affect the present and future of an organization.
- Organizations may be designed and manipulated. Humans can create an initial plan for an organization, and these plans can be adjusted during an organization's life.

We will begin by defining the concept of an organization. From there, we will discuss the common elements of multiagent simulation, and the representational choices that inform these models. After we describe important elements of models, we will discuss methods used to both inform and test models. Finally, we will explore common issues that face all modelers and model consumers.

What is an Organization?

The definition of an organization, as opposed to other collections of people, can be difficult to clearly enumerate. We find it useful to characterize organizations as entities that have:

- Multiactor membership: actors may or may not be human.
- Task-orientation: organizations are structured to perform work.
- Goal-driven behavior: tasks support goals. Goals may change over time.
- Agency: organizations can alter themselves and their environment, and be affected by external changes.
- Independent knowledge: organizational knowledge is not directly tied to the knowledge of individuals.
- Legal autonomy: individuals are not directly responsible for the actions of the organization.

As such, organizations are multilevel entities such that the structure of the organization can be represented as a series of interconnected networks (Carley, 2005). One of these networks, and perhaps the most studied network, is the human-to-human network, which typically operates at a formal or authority level and at an informal or friendship, advice and collaboration level. Another network that is particularly important from a cyber perspective is the information technology (IT)-to-IT network, which is comprised of all such technology, associated databases, and the electronic modes of communication among these. Connecting the humans and the IT is another network often realized over multiple types of media. Then there are the knowledge network that links the agents to the data available and the activity network which links the agents to their tasks. And there is the traditional task network, familiar to operations research, showing what needs to be done before or in conjunction with what. A coherent collection of networks that describe a single organization is referred to as a meta-network (Carley, 2002). The analysis of these meta-networks for assessing organizations is a growing field, and there are analytical tools, such as ORA (Carley, 2014), optimized for this type of analysis. Using such tools organizational units can be designed and their performance assessed.

Organizations exist, from a functional perspective, to organize individuals and resources to achieve goals not within the capabilities of any single individual. As such, collections of individuals must be brought together. Individuals cooperate and perform tasks in service of the organization's goals. The goals of an organization are distinct from the goals of any of its members, although they may be well aligned. Goals are set by organizational processes, usually involving the input of multiple decision makers. In the pursuit of their goals, organizations change themselves and the environment around them. These changes may or may not be in their favor. Over time, as the organization achieves goals, unique organizational knowledge is formed. This organizational knowledge is not a description of the current knowledge of its individuals, but is instead distilled from individual contributions over time and is often stored in an organization's standard operating procedures. In order to organize individuals to do work toward large goals, particularly those that may have consequences for others, members of organizations must feel protected from the legal consequences of the organization's actions – the organization must have legal autonomy.

As stated earlier, organizations exist to organize the efforts of individuals toward large goals. How do organizations attempt this? They do this by structuring the responsibilities, interactions, and incentives of individuals to maximize the alignment of an individual's capabilities and goals with the organization's needs. This is sometimes referred to as the 'design' of an organization. Because there are complex interactions between the environment in which an organization operates, the capabilities of its members, and the goals of an organization, there is no one optimal design. One goal of COT's research is in understanding the interactions between all of these factors and an organization's design.

Now that we share a common understanding of an organization, we now discuss multiagent simulations and the representational choices required of developers of these simulations.

Defining a Multiagent Simulation

To define a working organizational computational model, the modeler/theoretician must establish representations of the environment.

The environment can be roughly characterized based on four questions.

- Is time continuous or discrete?
- Is space physical or virtual?
- What is in the environment?
- How could the environment change over time?

The following subsections will attempt to describe common modeling choices to answer each of these questions.

Representations of Time

Time, in simulation, can be either continuous (like the real world) or discrete, where it can be separated into equal-sized pieces. We call these pieces 'turns.' In discrete-time (or turn-based) simulation, everything that can act may have an opportunity to do so once per turn. In continuous-time simulations, agents may take new actions as computing resources allow. Some effort is usually made (in competitive environments in particular, see below) to ensure that agents have roughly equivalent computational resources, but not necessarily. Games like risk, chess, and monopoly can all be viewed as turn-based simulation.

Turn-based simulation may seem like a gross simplification of the real world, rendering such simulations suspect, but in practice it is a relatively harmless simplification that makes problems of agent concurrency and computational resource access trivial. Turn-based simulations are appropriate when (1) actors should be expected to have similar opportunities to participate, and (2) when the phenomenon of interest occurs over long periods of time: hours, days, or months, as opposed to seconds or minutes.

Representations of Space

Space in simulations may be physical or virtual. If space is physical, then agents are placed at points on a map. Physical space may, like time, be continuous or discrete. Discrete space involves dividing up the area of the map into equal-sized chunks, often called tiles or blocks. Cellular automata exist in such tile-worlds, and Schelling's Segregation Model (Schelling, 1971) also used such a world, see **Figure 1**. Tile-worlds may or may not be connected at their opposite edges – if both edges are connected, a tile-world forms a ring torus, which can remove problematic edge effects.

Physical space in simulations is useful if the theory requires it. A simulation examining, for example, how people interact as they move about an office building will require some idea of physical space and of entities moving through it and interacting with other entities. Typically, simulations with physical space use it to constrain agent perception and interaction.

Often in organizational models, space is virtual – entities are not placed in physical space. Instead, connections are drawn between entities that indicate who may affect and/or interact with who. These connections can be represented as networks, matrices of who is connected to whom, where '0' indicates no connection and '1' indicates a connection, as shown in **Figure 2**. Modern simulations often use multiple network semantics to enrich the virtual environment.

Figure 1 A tile-world, with agents in blue. On the right, Manhattan distance is shown relative to an agent on the top-left.

Figure 2 Networks are a convenient and useful representation of virtual space environments.

Virtual environments are useful when physical adjacency is not a primary driver of interaction in the simulation. For example, interactions between people doing knowledge work may be more driven by work responsibilities rather than physical adjacency. Virtual environments, like physical ones, are used to constrain agent perception and interaction possibilities.

Elements in the Environment

What exists within the simulation environment? This is a fundamental choice that should be driven by theory. Because organizations are goal-driven entities, organizational learning models usually include some representation of agents, knowledge, and tasks. Although an organization, as a whole, may be said to have some particular piece of information, that information may not be where it can be usefully applied (as defined by tasks). Thus, one common method of evaluating simulated organizational performance is through examining the agreement between three networks (although they may not be represented, explicitly, as networks by the modelers). These three networks are the knowledge network (who knows what), the assignment network (who should do what), and the requirements network (what knowledge is needed for what), as shown in **Figure 3**.

Not all organizational models include explicit representations of these three objects, but their presence is often implied in the theoretical descriptions of the model.

Agents

Usually, agents are representations of humans, but some simulations allow the set of entities to include nonhuman objects, such as IT systems, and may also include entities at different levels of granularity, an agent representing a single individual may interact with an agent representing a team of individuals.

Entities that can affect their own state or the state of others have agency. We refer to these entities as agents. Entities without agency will usually be referred to as objects. Agents may act on objects, but objects do not act directly on

Figure 3 Three common objects within an organizational model are agents, knowledge, and tasks.

agents, although their presence may alter the actions chosen by an agent.

Agents have bounded rationality, limited access to the state of the larger world in which they inhabit. There are various limitations that can be prescribed to these agents, usually based on the larger theory of interest and drawn from human limitations. Agents may be only able to access state for things they can directly observe. They may forget knowledge they acquired earlier. They may have a limited number of refinement cycles before a decision must be made. Their perception of state may be error prone. Agents should have one or more of these limitations to be useful in a multiagent simulation.

Following directly from bounded rationality, agents also have limits to the possibilities available to them in their social interactions (Simon, 1991). Formal and informal mechanisms frequently prevent individuals from interacting with each other. Although it may be theoretically possible for the mailroom assistant to interact with the CEO of a Fortune 500 company, such interactions are unlikely to be routine and often may be safely discounted. Organizations often seek to impose structure to effectively distribute coercive, reward, and legitimate power (French and Raven, 1959). Individuals, in order to protect their own social capital, often seek to prune social ties for their own benefit (Burt, 1992, 1997). Thus, useful models of organizations will frequently limit interaction possibilities for their agents.

Agents must have actions available to them to be classified as agents. Again proceeding from theory, a modeler must define the actions available to agents and the decision heuristics used to select actions. Actions may be destructive (attacking another agent) or nondestructive (sharing knowledge with another agent), but all actions must have consequences that may alter future behavior of this or other agents.

Some models have entities that represent individuals but do not allow these representations to take independent action. Instead, a single model controller, which represents the organization, acts upon these agents. March's Mutual Learning Model (1991) is an influential example of such a model.

In Construct, agents may choose an interaction partner from all-available alters. They share knowledge with these partners, which may alter the partner's perception of the agent. The choice of who to interact with is weighted by two dynamic drives: (1) the desire to interact with alters similar to the agent, and (2) the desire to interact with alters who appear to have rare knowledge. Because of these two drives, the act of sharing knowledge will change the probabilities for both agent and alter of who they will interact with in the future.

Knowledge

Knowledge is information useful to the agents, either informing their choices of actions or helping them to complete tasks. Knowledge may be represented in a variety of ways; some methods include access to resources, rules that constrain an agent's actions, elements of the state of the environment that the agent can perceive, and as bits in a bit string. Organizational knowledge and individual knowledge may have different representations in the same simulation. In simulations where knowledge is represented as an explicit object, it is usually assumed to have some evidentiary basis – it is not merely an opinion. The transfer of knowledge, unlike other material resources, does not deplete the donor's store. Agents may not know, however, what they know.

In Construct, agents have two separate knowledge representations. The first is the model's ground state, what agents knows what, represented as multimode Agent x Knowledge matrix. Construct agents also have a perceptual matrix of what they think other people know, each agent thus has their own Agent x Knowledge matrix.

Tasks

Tasks are activities that are expected to have some useful larger purpose for the organization. They are not identical to goals, but may be instrumental in completing goals. Alternatively, they may be present in simulations where goals are never modeled or discussed.

Task performance may be dictated by agent actions, or may be inferred from agent characteristics. Task success is usually not guaranteed: it may be informed by agent knowledge, by exogenous probabilistic interference, or by third-party constraints.

In Construct, task performance is determined by access to knowledge relevant to the task. Tasks are assigned to agents at simulation run-time, and their performance is assessed each turn. Because tasks in Construct are assumed to be knowledge intensive, they are modeled as binary information tasks, if the agent has a majority of the required information for the task, the agent succeeds. If not, they fail at the task.

Current Research

In this section, we introduce some of the new trends in COT research. We discuss three trends: multimodeling, multilevel modeling, and rapid model development.

Multimodeling and Model Interaction

Multimodeling is an effort to leverage previous modeling work by incorporating one or more models into a single unified process. There are four ways models can be linked together on the basis of how they are connected by inputs and outputs, these are (1) integration, (2) docking, (3) interoperability, and (4) collaboration (Carley et al., 2012) as shown in **Figure 4**.

Integration, which involves refactoring models so that they work within a single common system envelope, is the most obvious but also most expensive method of integrating models. Representations of the phenomena must be aligned for all models, and this process often involves significant investment in new development work.

Docking (Axtell et al., 1996) is an approach to model validation where two models of the same phenomenon are directly compared on their features and their results. Docking two models require those models to have a common input and a common output. Model results are compared on three increasing levels of equivalence: relational, statistical, and numerical. Beginning with numerical equivalence, this is where one model produces the exact same numbers as the comparison partner, the two models can be, essentially, swapped interchangeably across tested values. Statistical equivalence is a characteristic of two models that they produce

Figure 4 Multimodeling methods 'D' stands for data. A line is drawn from data to a model if it is input to that model, and a line is drawn from model to data if the data is an output of that model.

functionally identical results across tested values. Relational equivalence is where two models do not produce identical values, but instead produce similar patterns of output value across tested input values. Relational equivalence is usually considered sufficient to say that two models are docked to each other, because model inputs, although notionally similar, are rarely perfectly matched in the granularity and responsiveness of the input data.

Collaboration, like docking, involves two or more models that take in a common input, but do not produce similar outputs. Instead, both models take the input data, along with other data, and use that to predict different new data. Models can be easily made collaborative by matching the representations of their input data.

Interoperability is the idea that the outputs of one model can serve as inputs to another model. This is a useful and often inexpensive technique, particularly when building one model to extend and leverage the power of an older, more established model, because the data representations both required by and outputted by the older model are well understood. It is one approach that can lead toward Integration (where the models are in the same system envelope), but can be useful as part of a looser confederation of systems.

Multilevel Modeling

Multilevel modeling is an effort to account for both group and individual level effects concurrently within a model. Issues in multilevel representation have been central to organization science research (Rousseau, 1985). Statistical methods have found some success in grouping observations according to larger real-world structures (Snijders and Bosker, 2012). These methods help account for observations that, due to the inherent grouping of subjects within the frame of the research question, were not completely independent, such as students within a common classroom.

Within the modeling conducted in COT, multilevel modeling is used to indicate that there are multiple levels of dynamic description within a single model. For example, the model may have 42 individuals, 5 teams, and 2 multiteam organizations, but the number or characteristics of higher-order descriptions (the teams and organizations) should change over the length of the simulation. These descriptive characteristics are important to the model's mechanisms.

There may be multiple levels of agency within a single model. The individual may take actions within their purview, and the groups, teams, and companies of which they are members may also take actions separately as autonomous entities. The actions of individuals may influence the actions of the team, but they are not the same action. The actions allowed to each level of actor are usually distinct, although there may be parallels.

Adversarial models, where individuals are members of teams hostile to each other, could be described as a multilevel model, but only if the condition of the larger group unit has an effect on the actions of the individual, such as in Morgan et al., 2010. Adversarial models, where the state of the group has no direct impact on the individual's state should not be characterized as multilevel models.

In Construct, individuals use their knowledge of a not well-known actor's group affiliations to interpret what that actor is likely to know. As they interact with these actors, their perception of these groups will change, which will affect their likelihood of interacting with other not well-known alters. In this way, Construct is a multilevel model.

Rapid Model Development

Models take time to build. As models move from highly theoretical and intellective exercises to an interest in modeling specific scenarios of interest, the timeline for development shrinks even as the modeling requirements increase. Models can be made completely irrelevant by events if their results are predicated on assumptions no longer valid. For example, the organization has restructured, or a key leader has left the company. Thus, this research work is driven heavily by the needs of applied model users.

Rapid model development takes lesson from object-oriented and data-driven development paradigms. Rather than explicitly enumerating all state objects within a given system, the model software defines interface standards and file formats that can be used to provide this state. This decouples the

model, which specifies how agents will interact with their environment, from the model's initial state. Modelers must still define behavior for both agents and the environment.

This decoupling provides practical advantages when attempting to apply a theoretical model to a given applied context. Data used to inform the model can either be generated from theoretically useful test conditions, or created by translation of real-world data into a format digestible by the model. This translation process, although nontrivial, provides an opportunity for channeling the enormous data created by social media into models.

On a theoretical basis, it also provides an important distinction between the model as an environment and the initial state of the model. The validation of a model without a data-driven element requires evaluation not only of the model's behavior but also of the model's initial state. Separating these elements allows for concerns about the model to be more easily addressed.

For example, Construct models have been informed by the analysis of news articles (Pfeffer and Carley, 2012), by field studies of teams (Schreiber and Carley, 2007), by doctrinal texts on organizations (Lanham et al., 2011a), from combinations of doctrinal and text-analysis work (Lanham et al., 2014), and from subject matter expert estimates (Lanham et al., 2011b).

Model Fidelity and Model Validation: Common Concerns

Any discussion of COT is incomplete without discussing the highly related issues of model fidelity and model validation. The decisions modelers take in choosing to represent a phenomena are not guided, intrinsically, by deductive processes. Rather, the process is a creative one. Modelers may make poor decisions. Understanding how to assess models is important for consuming model results appropriately.

Model Fidelity

Model fidelity focuses on the issues of actor and state representation. Models exist on a fidelity axis, ranging from highly theoretical intellective models, which simplify and abstract the environment of phenomena to their essentials, to highly emulative models, which attempt to reproduce as realistic an environment as possible, as shown in **Figure 5**. All models, of course, must abstract at some point. A perfect reproduction of the modeled object is not a model, it is the thing itself.

Figure 5 Balancing the fidelity needs of the simulation is an important modeling effort. Most computational organizational theory models are intellective.

High model fidelity (emulative simulation) is particularly important to simulations for use in training (Hays and Singer, 1989), although even intellective simulations can be useful for training in the business context (Van Ackere et al., 1993). The vast majority of COT models are intellective in nature.

Data-oriented design (as discussed in the rapid model development section above) blurs the line between emulative and intellective models. Models can be built with relatively simple behaviors available to both agents and the environment, but be instantiated with very complex and detailed initial states.

Questions of model fidelity that concern both a model developer and a model consumer are:

- Does this model include the factors I think are important to exploring this phenomena?
- Does this model include factors that I do not think are important to exploring this phenomena? Is it unnecessarily complex?
- Does this model ignore important interaction possibilities between agents and the environment?

Model Validation

Where model fidelity focuses on the questions of representation, model validation asks the question 'is this a good model?' By this, we mean 'does the model, given an initial state, produce reasonable behavior?' Of course, the answer is almost always 'it depends, how will the model's results be used?' Validation is thus tied, even more intrinsically than model fidelity, to the intended purposes of the model. Models expected to guide decision makers should be subjected to much more rigorous validation that models intended merely for discussion.

In the organizational theory domain, standard experimental assumptions do not hold. When making interventions on a real-world organization, it is rare for the experiment to be easily repeatable or for the results to be easily replicated. Experimental controls can be difficult to clarify, and gathering all necessary data is often infeasible or unethical. The difficulty of traditional experimentation makes a strong case for COT, but we should approach testing the resulting computational models with a similar level of rigor, evaluating them with 'virtual experiments.'

Virtual experiment methodology also makes some assumptions. It assumes the model's code is accurate, that the model has sufficient fidelity to the phenomena, and that standard statistical tests can be used to compare outcomes. Thus, questions of a model's fidelity should be addressed before a model's validation process even begins. Hopefully the modeler has considered the model's fidelity multiple times over the model's development period.

Validation, it should be noted, is hard. Model validation can require as much or more effort than the model's development. Human evaluators usually have some bias toward their products, and neutralizing this bias is difficult. Validation is knowledge intensive, requiring a deep understanding of the empirical phenomena being modeled (Louie and Carley, 2008). Validating agent-based COT simulations is also difficult because agent behavior is not predetermined and

path dependent – many simulation runs may be necessary to understand the full scope of possible system behaviors. Finally, the empirical data for validation may simply not be available at an appropriate granularity.

Validation can occur at multiple levels (Maxwell and Carley, 2009). The type of validity necessary for a model depends on its purpose (Burton and Obel, 1995). These levels are:

- **Internal validity**: the model's code is error free.
- **Parameter validity**: the model's parameters allow expression of all critical variables of the phenomenon.
- **Process validity**: the behavior of agents and the environment fit with current understanding of the phenomenon.
- **Face validity**: the results of the simulation, given the initial state, match the opinions of experts.
- **Pattern validity**: the outputs of the models show similar valence and magnitude of change across tested parameters to empirical data. It matches the pattern of the available empirical data. If abstracted, this is sometimes known as 'stylized fact validation.'
- **Value validity:** the outputs of the models show very similar values to those found in empirical data.
- **Theoretical validity:** the model correctly expresses a theory that explains the phenomena of interest.

Docking (Axtell et al., 1996; Burton and Obel, 1995) is also a model validation technique. A model that is docked to another model and has established relational equivalence (as discussed above), can make some claim to the pattern validity of the original model. Value equivalence, if achieved, would allow the docked model to inherit the value validity of the original model.

In multimodeling environments, validation of all the models at once can be difficult or impossible. Instead, inputs and outputs of these models are validated against real-world data individually, a process called *validation-in-parts*. This idea inherits from modern manufacturing process validation, which focuses on the outputs of the manufacturing effort, not on the mechanics of that effort.

Summary

In this article, we have introduced the area of COT. Research in COT explores the complex interactions between organizations and their members. Interesting behavior often emerges from the interactions and demands of modeled primitives, whether people or processes, although this introduction has focused on people-oriented simulation.

We have defined organizations as legally autonomous entities that attempt to achieve goals not within the capacity of any individual member. An organization's pursuit of its goals will change both the organization and the environment in which it operates, affecting other organizations (and themselves) either beneficially or adversely. Members of an organization do tasks, and both require and generate knowledge in the performance of these tasks.

To provide a useful introduction to COT research, we explored the requirements of defining and instantiating a multiagent simulation, using Construct (Carley, 1991a) as an illustrative example throughout. We discuss time, space, and elements within an environment, focusing on the importance of identifying agents and what actions those agents can take.

After identifying important elements to any single model, we discussed some important current trends in COT research. Multimodeling is an effort to leverage multiple models to provide a more complete picture of complex phenomena. Multilevel modeling allows actors at multiple levels of granularity to have important effects on actors at other levels. Rapid model development leverages data-driven approaches to software development: divorcing model behavior from a model's initial state.

Finally, we discuss important points every COT model consumer and developer should be aware of, issues of model fidelity and model validation. Model fidelity explores the issue of whether a model's representation of phenomena is appropriate, too simple, or unnecessarily complex for the phenomena of interest. Model validation asks whether the model is sufficient to the purpose for which it will be applied.

COT is a valuable and interesting area of research with important theoretical and applied areas. We hope this introduction has been useful.

Abstract

Since the early days of computer technology in education in the 1960s, it was claimed that computers can assist instructional practice and hence improve student learning. Since then computer technology has developed, and its potential for education has increased. In this article, we first discuss the changing terminology that accompanies the technological developments, followed by an overview of different types of applications of information and communication technology (ICT) for use in education. We then describe how different ICT applications align with different views on education. The potential of ICT for enhancing the curriculum as demonstrated in well-known studies is presented, followed by a picture of the actual use of ICT in education. Problems explaining the gap between potential and actual use are discussed.

The Need for New Conceptualizations of the Use of Computers in Education

Rapid changes in technology lead to changing conceptualizations of the use of computers in educational practice. In this respect, the term Computer Assisted Instruction (CAI) seems a bit obsolete, and closely connected to a specific type of computer use in instruction (Dede, 2008). CAI was adopted in the early days of computer use in education, indicating either a type of software program for education or a type of instructional process. However, the rapid developments in hardware and software ask for new terminologies and conceptualizations to study and discuss the potential of computers in education. The term computer technology, often used in the 1960s and 1970s, has been replaced by information and communication technology (ICT, mostly used in Europe) or information technology (IT) or technology (in North America). ICT refers to all technologies used for processing information and communication. Because of the integration of computers with communication systems including audio and video technology, terms such as multimedia or digital media are also being used. The development of computer technology from processing information to also supporting communication augmented its potential for education. In particular, the immersion of computer and other technologies in everyday life, as well as the different representations of technology (e.g., tablets, smart phones, robots), require educational researchers and professionals to rethink the potential of technology for education and the way it can be researched. Some therefore (e.g., van 't Hooft, 2008) prefer to speak about ubiquitous technology, to refer to the ever presence of technology in the environment but not typically seen or noticed. Although we realize that ICT has its limitations we will use this term in this article. We need to realize, however, that ICT is a broad concept. Its impact on curriculum, pedagogy, and student learning can only be discussed from the perspective of specific ICT applications, either hardware or software, that is being used in the teaching and learning process.

Software Applications for Educational Use

Introduction

Early software packages for education were mainly text based and used only simple graphics. This evolved in the 1990s and early 2000s to different combinations of modalities (pictures, moving images, sound, and text), often integrated into electronic environments. By then the increasing possibility to distribute information via the Internet was further explored and teachers were able to implement distance- or e-learning. As of 2003 the term "Web 2.0" emerged, indicating web applications that facilitate information sharing and collaboration on the World Wide Web. With Web 2.0, users are able to interact and collaborate with each other and generate their own content. Another development is cloud computing, which gained ground during the late 2000s. Cloud computing provides even more opportunities for teachers and students to work together online and it offers financial, administrative, and technical advantages. These new developments changed the way information is stored, distributed, and shared, but it has not made the more traditional software applications obsolete. The following types of applications are available for education.

Word Processor, Presentation Software, Spreadsheets, and Graphics Software

The software programs in this category are part of the basic application software of nearly every PC. They may support students in their learning process, because of their capability to structure information, and to easily present it in different modes. Research related to the use of word processors in education in particular shows the potential of this tool to stimulate students to write and to support the writing process. Presentation software is used to display information and it is therefore usable for organizing and presenting information, but also for (learning to) structuring information in such a way that people can learn from and work with it. Spreadsheets emerged as a potential tool for learning mathematics and science. Spreadsheets contain features for modeling situations, analyzing change, and linking key problem variables to tables and charts that can be presented visually. This provides teachers with tools to show science and mathematics concepts and processes, and gives students the opportunity to utilize these capabilities to gain a deeper understanding of the concepts and processes. Graphics software enables people to manipulate visual images. This can be incorporated in word processing, presentations, and the use of spreadsheets. The opportunities for manipulating images and using it for educational purposes have evolved rapidly in recent years. Not only the quality of the

images improved, but also the user-friendliness of the accompanying software. Even young children are able to work with graphics software, for instance while making mind maps about the topic that they have to learn about.

Drill and Practice and Tutorials

Drill and practice software is one of the earliest types of educational software and has as main purpose to let the learner memorize information (e.g., facts, language vocabulary). Most drill and practice programs will provide the correct answer after answering a question incorrect, so that the learner is not caught in a particular item for a too long period of time. The software often has facilities to provide feedback to the learners and to keep track of their performance. Tutorials can be used for learning new educational content, and the main purpose of tutorials is to instruct the learner. Tutorial software assesses the learner's knowledge and presents new instruction or gives a new practice based on the assessment of the learner's knowledge level. Newer forms of drill and practice and tutorials are adaptive tutoring software, intelligent computer assisted instruction (ICAI), and intelligent tutoring systems (ITSs). Traditional computer assisted instruction and tutoring systems operate according to an algorithm and provide sets of lessons, samples, exercises, and tests for the student. ICAI and ITSs diagnose the strengths and weaknesses of students, then adapt instruction to specific needs, and provide feedback through hints, examples, encouragement, and exercises that are appropriate for that specific student. ICAIs or ITSs reduce the time spent by teachers in grading and supervising. A main drawback of these systems is that the costs of producing them are high, and one of the main criticisms is that the systems do not really allow students to learn from their mistakes because the program guides them toward the right answer.

Simulations, Haptics, Games, and Virtual Worlds

Simulations are representations of a part of reality and provide learners the opportunity to engage in situations that would otherwise be too hazardous, costly, or lengthy to conduct in the classroom. Simulations could represent for instance certain behavior of a population or a set of processes. By manipulating variables in the representations and giving students the opportunity to visualize, model, explore, try out a variety of strategies, and study the effects, the students can gain an understanding of the reality. A review study about the use of simulations in science education showed that simulations enhanced with instructional support can have a positive effect on student learning (Rutten et al., 2012). A recent development is haptics, simulations in which also the sense of touch is incorporated. An example of this is hapTEL, a workstation that simulates clinical conditions for dental training (http://www.haptel.kcl.ac.uk/).

Games are competitive, situated, interactive learning environments based on a set of rules, and/or an underlying model, which with certain limitations and uncertain conditions, a challenging goal to be achieved. An educational or serious game is a game designed for educational purposes. Research has shown that the challenge to solve cognitive puzzles is the main motivation for playing games. The challenges in a game can be both visible and hidden. Visible challenges are for example the tasks that the player has to perform. Hidden challenges are discovering the unique rules, opportunities, constraints, and strategies of the game. To overcome the visible challenges, the player must first master the hidden challenges and in order to be able to do this the player must create a mental model of the obstacles built into the game world. This way of learning is very active, complex, and learner-centered. Educational or serious games have evolved vastly over the past decade. Examples of different kinds of games are computer games and massive multiplayer online games (MMOG). A well-known example of a multiuser virtual environment that fosters learning scientific inquiry and twenty-first century skills in middle grade students is The River City Project (http://muve.gse.harvard.edu/rivercityproject/). River City has the look and feel of a video game but contains educational content. While playing the students take on the identity of an avatar, communicate with other avatars, find hints and artifacts and have to define several hypotheses that have to be tested. The students learn principles and concepts of science, they acquire reasoning skills, and they carry out investigations that test their ideas. Such an environment is situated and authentic, which is important for fostering learning. Next to multiuser virtual environments other virtual worlds are emerging, such as MMOG, World of Warcraft and Metaverses, virtual worlds that are primarily social oriented. An example of such a world is Second Life. Second Life is a 3D online simulation where you walk around in the shape of an avatar, interact with others, buy property, etc. It is not intended as a game, but as a social space. This kind of virtual world offers many opportunities for education, from language to technical and marketing subjects, and there are currently hundreds of educational sites within Second Life.

Multimedia Cases

Multimedia cases offer the possibility to study parts of reality by presenting illustrations of real world practice that can be discussed and studied from several perspectives. Multimedia cases usually combine video segments, audio, and textual commentary together with random access facilities and hyperlinks, and so create an open-ended student-centered learning environment. Though used in many fields of study, they are increasingly used in teacher education for studying the complexity of the classroom from various viewpoints. In this context, multimedia cases provide the potential to incorporate contextual, theoretical, and pedagogical information into a rich and multilayered representation of classroom teaching (Voogt and Knezek, 2008).

Web 2.0

With Web 2.0 users are able to interact and collaborate with each other and to generate their own content. Examples of Web 2.0 include social networking sites, blogs, wikis, video sharing sites, mashups, and folksonomies. Social networking sites are online sites that focus on building social networks and relations among people, who share interests and/or activities with people having similar interests. This phenomenon gains interest of educators. They use social networks (Facebook, Ning, Wiki, etc.) as a communication tool, partly because they know that many students are already using a wide range of

these applications. The fact that many people use social networking as a means of communication brings concerns in relation to giving out too much personal information and the control of data; information can be altered, removed, or passed to third parties. The debate on how to deal with this in education has just begun.

Augmented Reality

Augmented reality (AR) is a view of a real-world physical environment or object, whose elements are augmented (supplemented) by computer-generated input such as sound, video, graphics, or GPS data. As a result, the technology enhances one's perception of reality. Typically, users have special equipment such as a heads up display, goggles, or a special computer. In education, this can be used to simplify complex tasks by inserting additional information into the field of view, or by for instance creating virtual objects in museums and exhibitions to explain certain objects that are physically present in the exhibition. An example of using AR in education is Handheld Augmented Reality Project (HARP) (http://isites.harvard.edu/icb/icb.do?keyword=harp), a project in which handheld computers and GPS receivers are used for middle school math and literacy curricula that use AR to deliver instruction in the form of games. These games are played in a real physical location, and on their handheld a map is displayed with a layer of digital objects and virtual people who exist in an AR world superimposed on real space. This creates a learning environment that stimulates the students to explore and to solve various mysteries and problems. Exploring and solving these problems impose active learning and new means of information gathering and communication.

Data Logging and Modeling

Data logging (formerly also called Microcomputer-Based Laboratories) is an application particularly useful for science education. Specific hardware added to a PC or a handheld computer in the form of probes allows for real-time data collection. It becomes much easier to repeat experiments, to measure different variables at the same time, to use a very short-time or a very long-time range, to analyze data, and to represent data graphically. Data logging can be used to collect and analyze data (temperatures, light intensity, motions, etc.) and may support students in their laboratory work. Instead of spending instructional time on data collection, it can be used for analyzing and interpreting data. However, to get an in-depth understanding in the relationship between variables, it is important to model these relationships. Modeling software supports learners in constructing their own models or adding to part-built models. Depending on the modeling environment this may involve: specifying formulae; writing a program in a simple programing language or manipulating a graphical or pictorial modeling language.

Views on the Use of ICT in Education

It is generally accepted that ICT as such does not support learning. The full potential of ICT for learning may only become realized when ICT is well integrated into a learning environment. In the early days of computer use in education these learning environments were narrowly defined, and referred to the computer software that supports certain types of learning. However, in more recent definitions, learning environments are considered dynamic complex systems, in which people (teachers, students, and others), media (including ICT), and the architecture of the (physical and/or virtual) environment interact (Voogt and Knezek, 2008). Dede (2008) provides an overview on how ICT was understood and used by different theories of learning. The 'narrow' view of an ICT-enhanced learning environment is represented in behaviorist and cognitive theories of learning. In the behaviorist perspective ICT applications, such as drill and practice and simple tutorials, were applied to master factual knowledge and (routine) skills at learner's own pace, and so allow for individual learning trajectories. Meta-analyses report small effects on student learning for these kind of applications. Cognitive theories of learning, also allow for individual learning trajectories but focus on cognitive understanding of complex concepts and skills. In this approach, ICT applications, such as ITS, based on artificial intelligence were developed to assist the learner in developing algorithms and heuristics needed to solve well-defined complex problems for specific subject domains. The effect sizes are somewhat higher than the ICT applications based on behaviorist theories of learning (Dede, 2008). Finally, constructivist theories of learning assume that the learner has to construct new knowledge and understanding through active participation in the learning process, eventually together with other learners or experts. In this approach, learning environments are more broadly defined and created in such a way that they allow for authentic learning and learner-centered education. Dede (2000) argues that ICT applications from a constructivist perspective of learning may contribute to

- The realization of a curriculum that is centered around real-world problems.
- Involve students in virtual communities of practice.
- Use advanced tools similar to those in today's high-tech workplaces.
- Facilitate guided, reflective inquiry through extended projects.
- Utilize modeling and visualization as powerful means of bridging between experience and abstraction.
- Enhance students' collaborative construction of meaning via different perspectives on shared experiences.
- Include pupils as partners in developing learning experiences and generating knowledge.
- Foster success for disabled and disenfranchised students.

A broad range of ICT applications can be incorporated in constructivist learning environments, such as general productivity tools (e.g., wikis, blogs, spreadsheets, the Internet), specific ICT applications to help individual learning (e.g., simulations, data logging, multimedia cases), as well as ICT applications that support collaborative learning (e.g., discussion forums, shared workspaces, virtual worlds). Because of the wide range of applications and settings there are no meta-analyses available that provide information about the effect of ICT-enhanced constructivist learning environments on student learning. However, several studies, such as the Jasper

Woodbury series (The Cognition and Technology Group at Vanderbilt, 1997), which was one of the first ICT-enhanced learning environments designed from a constructivist perspective, have shown effects on student learning.

ICT-Enhanced Learning Environments in the Curriculum

Several ICT-enhanced learning environments designed from a constructivist approach to learning have been studied for more than 15 years and have shown the potential of ICT to support student learning. They offer insights in the way ICT-enhanced learning environments need to be designed, in order to realize its goals. Knowledge Forum from Scardamalia and Bereiter (2006) is an environment to support students in collaborative knowledge creation in many domains. The work of Linn and colleagues (e.g., Linn and Eylon, 2011) in the domain of science education is an eminent example of an ICT-enhanced learning environment in the science domain. The Web Integrated Science Environment (https://wise.berkeley.edu/) focuses on concept learning through inquiry and collaboration. De Jong and colleagues (e.g., De Jong, 2006) studied the potential of simulations for inquiry learning in science education. They found that scaffolds and cognitive tools are needed to support the acquisition of the generation of hypothesis, prediction, and the exploration of models. These examples show what key characteristics for ICT-enhanced learning environments are: the provision of an infrastructure for collaboration between students and between students and their teacher, and scaffolds to facilitate collaboration, knowledge building, and metacognition (Voogt and Knezek, 2008). These classic studies are well documented and have demonstrated the added value of ICT for teaching and learning. However, despite their long history, they did not become part of main stream education.

Current Use of ICT in Schools

Recent large-scale international studies provide information about the current use of ICT in educational practices in different countries around the world. Data from the Second International technology in Education Study in 2006 from teachers teaching grade 8 (14 years of age) science classes showed that about 30% of the teachers did not use ICT, while about 20% use ICT on a weekly basis (Voogt, 2009). However, differences between countries are large. In Canada, Chile, and Hong Kong about 40% of the science teachers use ICT on a weekly basis, while in South Africa, Japan, and the Slovak Republic less than 10% use ICT so frequently. Results from the 2007 study of Trends in Mathematics and Science Study (TIMSS) (Mullis et al., 2008) showed that computers are hardly used in more than half of the lessons in eighth grade mathematics education (the international average is about 3% for the countries participating in TIMSS), despite the availability of computers. In fourth grade (9 years of age) mathematics, the use of ICT is also infrequent. Most use in fourth grade mathematics classes is for drill and practice (international average is 6% for use in half of the lessons or more),with exceptions for The Netherlands (30%) and Scotland (20%). The 2006 study of Progress in International Reading Literacy Study reported that about 30% of the fourth grade students had used computers to support reading instruction, and 39% of the students had read stories or other texts on the computer (Mullis et al., 2007). Also here the differences between countries are large. While in Austria, Singapore, Norway, and Hong Kong 60% or more of the students were supported by computers during reading instruction, in Georgia, Iran, Morocco, Moldova, and Macedonia 5% or less of the students were supported by computers. The picture that the results of these international monitoring studies tell us is that the immersion of computers in the curriculum is still scarce and shows a big gap between the expectations one might have about the added value of ICT for teaching and learning as found in research (see previous section) and the reality of the classroom.

Integration in Educational Practice

There is a variety of obstacles that hinder the use of ICT in educational practice. A major problem is the lack of communication and leadership between macro, meso, and micro levels in education. This lack of communication results in limited access to ICT in schools, problems with tuning ICT-enhanced learning environments with the curriculum, a lack of a shared vision at the school level and insufficient ICT integration competencies of teachers (Voogt and Knezek, 2008). Curriculum-related problems impeding the integration of ICT deal with the way ICT is present in national curriculum standards and student textbooks. Although many student textbooks nowadays have integrated software packages or links to Web sites, more advanced uses of ICT are often lacking. In addition advanced use of ICT requires more time than available in lessons periods of 45 min, in which many schools have organized their curriculum. These obstacles also refer to a broader discussion about curriculum goals, content, structure, and the role of ICT in a curriculum that matches requirements of the knowledge society (Voogt and Pareja Roblin, 2012). Research from Knezek and Christensen (2008) has shown that a teacher's use of ICT is affected by will (attitudes toward IT), skill (ICT competencies), and access to ICT tools. However, ICT competency cannot be not limited to basic ICT knowledge and skills. Meaningful use of ICT in education, however, requires teachers to develop knowledge and skills that enable them to integrate ICT with a suitable pedagogical approach for teaching specific subject matter in a certain context. Koehler and Mishra (2008) introduced the term Technological Pedagogical Content Knowledge to emphasize the importance of interaction between subject domain knowledge, pedagogical knowledge, and technological knowledge as a conceptual framework for describing the kind of competencies teachers need to integrate various ICT applications in their educational practice.

Determining Effects on Students

The ever-changing technology makes research into ICT in education difficult, complex, and challenging. This is particularly true for studying the impact for ICT on student learning.

The high expectations about the potential of ICT for student learning could not easily be confirmed by convincing evidence from research. The early meta-analyses from the 1980s reported moderate effects of computer-based treatments, compared to other instructional methods on student achievement, but many studies also did not find positive effects of ICT for students learning. Most convincing evidence for the effects of ICT is related to student learning in language arts, but the evidence with regard to student learning in math and science education seems less convincing (Voogt and Knezek, 2008). It appeared difficult to define the kinds of effects that were expected from ICT use, as well as ways to measure these effects. Initially, it was expected that ICT could enhance student achievement in traditional learning goals, but advanced uses of ICT aim to contribute to learning goals that are considered relevant in the knowledge society, such as higher order cognitive skills and so-called twenty-first century skills. These goals align with constructivist theories of learning. However, such learning goals require other assessment methods, such as formative and performance assessment (Voogt and Pareja Roblin, 2012).

Researching IT in Education

While early research on IT in education focused on the effect ICT applications may have on student learning, it was gradually realized that we also need to understand the way ICT is implemented in education to be able to assess whether and how ICT impacts student learning in the reality of the classroom. Compared to the early days of computing in education, research on ICT in education has become diversified and complex. While the teacher is considered to be a determining factor in the use of ICT in educational practice, much research is directed toward knowledge on factors that hinder or contribute to teachers' uptake of ICT, or to strategies that foster (pre- and in-service) teacher learning on ICT integration. To study the impact of ICT policy on the implementation of ICT in education, large-scale national and international monitoring studies are conducted, including international case study research to better understand the characteristics of innovative pedagogical uses of ICT. Next to research focusing on the implementation of ICT in education, technological changes result in new representations of knowledge (e.g., simulations, haptics, games) and new ways to construct knowledge (e.g., Web 2.0 environments). These technological developments require new and interdisciplinary approaches to study ICT in education.

Computer Games and Academic Achievement

Christopher J Ferguson, Stetson University, DeLand, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Research on the influence of video games on academic achievement has been controversial and inconsistent. Scholars have been examining the potential for both positive and negative influence of video games on academic achievement. As of yet, such research remains limited, controversial, and sometimes limited by methodological problems. Pathological gaming appears to be problematic for about 1–3% of children, although controversies remain on how to define and measure problematic gaming. Increasing attention has also been put into adapting video games for academic purposes. Initial evidence is limited but promising, although it is cautioned that scholars should remain conservative when discussing both positive and negative influences of video games on attention.

Since their advent in the 1970s, video games have been a source of considerable controversy and debate. Much of this debate has focused on the issue of violent content and whether such content increases aggressiveness (see Coyne et al., 2011; Ferguson, 2010, for competing views). Despite decades of research, debates on this issue have only intensified in recent years rather than being resolved. Although perhaps not as intense, debate has also focused on the issue of whether video games are associated with changes in academic achievement, either positive or negative (see Ferguson, 2011a; Gentile et al., 2012, for competing opinions). At present, debate continues regarding the potential of video games to positively, negatively, or not at all affect academic performance. The current article will begin by considering possible mechanisms for video game influence on attention, before turning to potential negative and positive effects in turn, including the issue of pathological gaming or gaming addiction.

Proposed Mechanisms by Which Video Game Might Influence Academic Achievement

One issue which has been recently raised in relation to the debate over video games and aggression is that of the *petition principia* or 'begging the question' logical fallacy in which a particular conclusion is assumed as the premise for conducting inquiry (Bennerstedt et al., 2012). This issue has also been defined in light of *moral panic theory* in which presumed harms about video games drove much of the research (which particularly conducted by investigators highly invested in the 'harm' view and sometimes funded by antimedia advocacy groups); such research claimed support for the initial premise, sometimes despite the actual data (Ferguson, 2010). Particularly in light of the recent Brown vs EMA decision (2011) as well as government reviews by Australia (2010) and Sweden (2011) which were critical of the violent game/aggression research, it is imperative that scholars remain aware of this 'tail wags dog' problem in other realms of video game research. In another way, the issue has emerged that scholars and activists have been quick to blame video games for all manner of social ills, often on the basis of weak and methodologically unsound data.

When it comes to video game effects on academic achievement the most obvious model for such effects is the "zero-end sum game." That is to say, any time spent on video games is time taken away from participation in other activities, particularly academic ones. Particularly given that the intrinsic appeal of academic work is certainly less than for video games, this approach makes a considerable amount of sense. Indeed most scholars would agree that moderation in the use of video games (as in all things) is a key feature of successful use of them. Research supports that moderate users of video games tend to be psychologically more healthier than either nonusers or extreme users (Allahverdipour et al., 2010; Kutner and Olson, 2008). Perhaps not surprisingly, this effect appears to hold for academic achievement as well (Ventura et al., 2012). This position can be taken to an extreme, however, in asserting that all or most of a child's free time should be focused on academics, and there is little 'value added' to allowing teens any time to engage in 'frivolous' pursuits.

A somewhat more extreme theoretical model is the 'brain damage' model in which the use of video games is thought to directly cause damage to the brains of players (e.g., Sax, 2007). Rather than merely asserting that video games distract from more worthy pursuits, this perspective asserts that the simple act of playing video games causes biochemical and physical alterations to brain structure, which are harmful. Proponents of this perspective tend to use the more extreme and frightening language of 'brain damage' or 'rewiring the brain' and this perspective is particularly popular among anti-video game advocates, who sometimes have funded some of this research (e.g., Center for Successful Parenting, 2011). Some scholars have claimed that video games, like other entertainment media, may induce attention problems by creating expectations for the brain to process smaller bits of information than are typical in traditional academic settings (e.g., Gentile et al., 2012), although this perspective has also been controversial (Ferguson, 2011a). Nonetheless this approach is less extreme than the general 'brain damage' perspective. The notion that video games cause damage to the brain was largely discredited by the US Supreme Court during the Brown vs EMA case (2011) and is arguably more the product of moral panic than good science (Ferguson, 2010).

Potential Negative Influences on Academic Achievement

Despite the various concerns about video games on academic achievement, relatively little literature has investigated this issue (Blumberg, 2011). That what exists has generally been mixed.

Theories of how video games negatively influence attention take two forms. The first is the 'zero-end sum game' approach in which video game use simply is time taken away from cognitive tasks that may foster academic achievement. From this line of thought, some studies suggest that children who engage in problematic gaming behaviors have reduced academic functioning. For instance, Chiu et al. (2004) found that Chinese children with problematic gaming behaviors tended to have reduced academic performance. However, not all studies have found a relation between problematic gaming and academic performance (e.g., Desai et al., 2010). Nonetheless problematic gaming may remain an important risk factor for low academic achievement.

A second theoretical approach has focused on the possibility that the fast action and clip of video games (and television) may make it difficult for children accustomed to such stimulation to slow down and pay attention to less stimulating academic material (Swing et al., 2010). In essence this approach suggests that the brains of young people become accustomed to fast-paced stimuli and are thus quickly bored or turned off by slower paced stimuli. Swing et al. (2010) propose this in examining video game effects on academics, although they note that the research on television had been mixed. Although this model is generally used to imply that video games cause harm in this regard, it has been reversed by some advocates of video games (e.g., McGonigal, 2011) to imply that the problem lies with the poor and static quality of academic learning rather than video games. In other words video games should not be blamed for being stimulating; academics are at fault for not being stimulating enough. This approach is the 'gamification' approach which advocates changing real-life activities such as work or school to greater resemble the reward structure of video games so as to increase achievement.

In one of the first studies of this phenomenon, Swing et al. (2010) conducted a short-term prospective study of video game and television use and attention and academic problems in a sample of school-age children. The authors concluded that time spent playing video games contributed to attention and academic problems a year later. However, this study has been criticized on several fronts (Ferguson, 2011a). First, the authors did not use well-validated outcome measures. It has now been established that the use of poor and unstandardized measures in video game research is associated with spurious effects (Ferguson and Kilburn, 2009). Thus the potential for a type I error from this study is very high. Furthermore, the effects found, while statistically significant, were very weak, below effect size thresholds for 'trivial' effects.

Ferguson (2011a) in a correlational study of youth found that, with other factors well controlled and using well-validated outcomes, measures such as the child behavior checklist, video game exposure, either in times playing or in violent exposure, were not associated with attention problems or reduced academic performance. Gentile et al. (2012), in turn, suggested that these null results might have been due to inclusion of too many covariates, such as antisocial personality. Gentile et al. (2012), for instance, suggested that there was little theoretical reason to control for antisocial personality, neglecting to note that antisocial personality has long been linked with academic problems and that, indeed, it was a significant predictor in Ferguson (2011a). Furthermore Ferguson, 2011a, had none of the multicollinearity problems that would give credence to Gentile et al.'s comments and reducing the analysis to a small set of basic covariates did not change the outcome.

In a more recent study examining college students rather than children, Ventura et al. (2012) found a complex relationship between personality, video gaming, and academic performance. Students who tended to play moderate amounts of games highly enjoyed tended to fare best in terms of grade point average (GPA). As for specific genres, preference for social media games (i.e., Farmville) and first person shooters were weakly ($r = -0.13$ and -0.14, respectively) related to reduced GPA, but not for seven other genres of games. Also these last results are for *preference for genre* not time spent playing. Overall, results did not support a link between time spent playing video games and academic problems.

Thus debate on this issue remains. There is no clear answer to the question of whether video games contribute in any way to academic problems. However, it is worth noting that none of these studies suggests a moderate or strong effect on academic performance. At worst the influence of video games on academic performance is quite small.

One possibility is that by focusing on time spent gaming, researchers may have failed to distinguish between healthy gaming and pathological gaming, or gaming behaviors which interfere with other life responsibilities. Thus, it may be that although video game use in general is a poor predictor of negative outcomes, pathological gaming may nonetheless be a predictor of negative outcomes related to academic achievement (Ferguson et al., 2011).

Pathological Gaming

Although a direct link between video game use and academic achievement by and large difficulties has sometimes been investigated, as noted above, by large research, which finds such links are weak and inconsistent. This has lead to some scholars considering that it may be more fruitful to examine processes by which some gamers may develop academic problems whereas others may not. In this sense, video games may become involved with existing mental health problems, whether exacerbating them, or simply becoming symptomatic of these underlying problems. For some individuals, video game play may become obsessive, interfering with other life responsibilities and activities including academic work.

This phenomenon is sometimes called pathological gaming and sometimes video game addiction (pathological gaming will henceforth be used). Although pathological gaming has got the attention of scholars over the last decade, much debate and discussion remain regarding how to define it, how to measure it, how prevalent it is, and whether it is a unique phenomenon

to video gaming, or merely symptomatic of underlying mental health problems. As such, at present, pathological gaming is not slated for inclusion in the fifth edition of the *Diagnostic and Statistical Manual of the American Psychiatric Association*.

Because of difficulties in understanding how best to define and measure pathological gaming, prevalence estimates have ranged widely. Gentile (2009), for instance, suggested that just over 8% of youth exhibit signs of pathological gaming. However, as this sample was Internet based, it is likely to be spuriously high as heavy Internet users may have been more likely to both respond to the survey and exhibit signs of pathological gaming. Further Gentile uses a measurement approach which is based on symptoms of pathological gambling behaviors. A number of studies have used this approach in which it is assumed that symptoms of pathological gambling are easily transferable (with minor wording changes) to pathological gaming. These might include items such as 'I think about gaming when I am not playing' or 'I use gaming to relax' or 'I have gotten into arguments with others related to my gaming.' Thinking about gambling when not gambling, using gambling to relax, or getting into an argument with one's spouse over considerable financial losses due to gambling are obviously problematic. But it is less clear that these same questions transferred to gaming behaviors are problematic. Thinking about one's hobbies (including gaming) when not involved in them, using hobbies (including gaming) to relax, are certainly normative. Given that kids and parents routinely argue over time spent on hobbies or entertainment, it is also unclear that arguments in this case are indicative of problematic behavior. As such attempts to directly build pathological gaming measurements on items cribbed from pathological gambling have been criticized by some scholars as flawed (Ferguson et al., 2011). Specifically, in a meta-analysis, Ferguson et al. found that studies relying on such measurement tools tended to have spuriously high prevalence estimates and correspondingly weak associations with expected mental health and academic outcomes. In other words, attempts to use the 'pathological gambling analogy' vastly overidentify normal individuals as pathological.

Other scholars have focused on the degree to which symptoms interfere with other functions. Example items of this type might include, 'I have sometimes continued gaming so long I missed work or school' or 'I have difficulty balancing video gaming time with studying.' Such items tap into the degree to which gaming behaviors interfere with work, school, relationships, and other behaviors such as exercise. Generally these studies find much lower prevalence rates and these items tend to be better associated with mental health problems in the real world (Ferguson et al., 2011). For instance, Desai et al. (2010), examining children in the United States, found that video gaming in general was not particularly related to negative outcomes involving aggression, mental health, or poor academic performance. However, a subset of children, approximately 3–4%, exhibited problematic gaming behaviors and were prone to more severe behavioral and academic problems. Van Rooij et al. (2011), using a sample of Dutch children, found the prevalence rate to be closer to 1.5%.

From this it is clear that how one decides to measure and define pathological gaming can have dramatic influences on prevalence estimates. This is particularly an issue where video games have been subject to moral panics (Ferguson, 2010) in which the fear of video games may propel exaggerated claims of potential harm. This potential for moral panics has been raised as a potential concern for pathological gaming (Barnett and Coulson, 2010). Advocates (including some scholars) who have invested in anti-video game views can be expected to selectively report prevalence estimates at the higher end of the scale, even where these may be less valid. Given that scholars still actively debate the meaning of pathological gaming (Griffiths, 2008; Wood, 2008) it is important for scholars to tread carefully in this area.

Related to this issue is whether pathological gaming is a unique condition or merely symptomatic of underlying mental health conditions. For instance, some individuals may essentially have 'addictive personalities' in which any pleasurable activity may be overdone to the detriment of less pleasant but pragmatically useful activities such as work and school. On this issue, not unexpectedly, much debate remains. Desai et al. (2010) suggested that it is more likely that pathological gaming is a symptom of underlying mental health problems rather than a unique condition brought on by video games themselves. This view was supported by the meta-analysis of Ferguson et al. (2011). However, other scholars (Gentile et al., 2012) suggest that effects may be bidirectional. At this juncture relatively few scholars appear to be suggesting that pathological gaming is likely to result in individuals who are otherwise psychologically healthy. The debate appears now to focus on whether video games are *particularly* prone to addictiveness relative to other pleasurable activities. Some scholars claim, for instance, that video games use an intermittent reinforcement schedule which makes them prone to addictiveness (Strickland and Doan, 2012). However, it is important to note that when media are at the focus of moral panic, it is quite common for advocates to suggest reasons why new media might be *particularly* bad. For instance, with video games it was sometimes suggested that their interactive nature might make gamers particularly prone to imitating the violence. This suggestion continued to be repeated even after having been discredited, turning it into a form of scientific urban legend (Ferguson, 2011b). Thus, once again, we must be careful to distinguish plausible but advocacy-driven rationale from scientific fact. At present, although there is considerable research linking pathological gaming with negative outcomes related to academic performance, uncertainty remains regarding causal directions (Kuss and Griffiths, 2011).

As a further issue, some scholars have identified the issue that it is important to distinguish pathological gaming from healthy engagement (Charlton and Danforth, 2007). That is to say some players are *engaged* and may play for fairly long hours without their game play interfering with other life responsibilities. This distinction between engagement and pathological gaming may help to explain why hours spent gaming is typically a poor predictor of academic performance.

As such the issue of pathological gaming remains controversial on many fronts. Most scholars in the field agree that some form of pathological gaming probably exists. But considerable disagreement about how best to define and measure it means considerable uncertainty will persist for the near future.

Potential Positive Uses of Video Games in Academic Achievement

As might be expected, and certainly as predicted under moral panic theory, most of the attention on video games and academic performance has focused on the potential for negative effects. However, several avenues of research have examined whether video games may have a positive effect on academic achievement as well. Some scholars have investigated the use of both educational and commercial games in academic settings. Given the popularity of video games, teachers and scholars have expressed considerable interest regarding the potential use of video games in academic settings. Some scholars have suggested that video games may prove to be socially and academically revolutionary (McGonigal, 2011) although it should be cautioned that just as fears of video games were prone to hyperbole, the same may be true for hopes.

Considerable attention has focused on 'serious' games, that is, games which are specifically designed with a particular education, social, or behavioral goal in mind rather than being simply commercial and entertaining (Annetta, 2010). As Annetta notes, such games must strive to engage students given that they compete with commercially available games for student attention. Such games function by providing an immersive and interactive environment for students to enjoy in which useful educational information may also be embedded. Such games have the advantage over traditional education by holding student attention on enjoyable activities while providing education.

This is particularly the case where recent discussion among scholars have suggested that educational settings may have to shift how they teach in order to fully prepare students for an increasingly technological world (Anderson, 2012). In other words, the next generation of young workers will increasingly be expected to be proficient with technology and those who are prepared will have an advantage over those who are not. Much of the attention has focused on fields related to science, technology, engineering, and math which tend to be relatively low enrollment among US students. Some initial work has indicated that video games designed to teach science material provide advantages over traditional instruction while also preparing students for the use of modern technology (Annetta et al., 2010).

The game *Immune Attack* (Howell, 2005) provides one example of an educational serious game. Immune Attack provides simulations of the human immune system in which the player must use a variety of weapons based on immune functions and medicine to fight a host of invaders and threats. Produced by the Federation of American Scientists, Immune Attack is currently being evaluated for its successfulness as a learning tool. Other scholarship has suggested that serious games may be positive for educational purposes in fields such as history (Watson et al., 2011), urban planning (Thomas and Hollander, 2010), engineering (Coller and Scott, 2009), and health and physical education (Papastergiou, 2009). Nonetheless our understanding of how video games may contribute to or assist in a full paradigmatic and pedagogical shift to the use of new technologies in education remains poorly understood. Serious games face particular challenges in retaining student engagement when students may be expecting production values similar to those found in commercial games, despite that serious games typically must endure a slower and longer cycle of production and use (Boyan and Sherry, 2011).

Attention has focused as well on the applicability of commercial games as positive developers of academic achievement. Although commercial games are not typically intended as educational tools, some either directly or indirectly include content that may foster academic achievement. For instance, games that focus on historical strategy such as *Europa Universalis* or *Civilization* may either directly increase knowledge of history related topics, or may increase interest in these topics. For instance, Moshirnia and Israel (2010) found that a slightly modified version of *Civilization IV* was effective in imparting historical knowledge in students.

One scholar who has been the most active in this area is Constance Steinkuehler who, at the time of this writing, serves as the US White House's expert on video games. Her research has indicated the commercial games such as *World of Warcraft* promote literacy and verbal learning through participation in verbal activities in the game as well as part of discussion and message boards about the game (see Black and Steinkuehler, 2009). Thus, although probably never the intent of the video game producers, the interactivity and community built up around the game, in this case a massively multiplayer online game, fosters the kind of engagement and dialogue that promotes verbal learning.

Nonetheless, research on the applicability of video games, whether commercial or serious, remains relatively nascent. Just as we have learned we must be careful about exaggerating negative effects, so too we must be careful in overstating positive effects. For instance, in the realm of visuospatial cognition, a number of studies have suggested that video games might promote this type of learning (see Dye et al., 2009, for a review). However, other scholars have suggested that the visuospatial cognition literature may suffer from many of the same flaws as the negative effects literature (Boot et al., 2011) and not all empirical studies have supported the existence of positive effects (Valadez and Ferguson, 2012). Thus, as with the negative effects literature, scholars are well advised to remain conservative in their language when discussing the potential for positive video game effects.

Concluding Statements

The issue of whether video games contribute to academic success, either positively or negatively, remains a controversial one. There have been competing pools of research to suggest that video games may either enhance or impinge upon academic achievement. None of these research is beyond debate. It is possible, as often happens in the early stages of research in a new field, that biases tended to favor 'effects' hypotheses in both directions. That is to say that it is possible that both the benefits and risks of video games for academic achievement may have been exaggerated. This is not to say that no effect exists, rather that they may be more subtle and idiosyncratic than sometimes implied in the scholarly literature. Whether video games are beneficial or harmful may depend as much on the individual child. Thus, attempting to formulate

'one size fits all' recommendations to parents or policy makers may be doomed to failure. There is value in providing information to parents of course, but ultimately they may be the best arbiters to what is most beneficial to their individual children.

It is important that we recognize that during 'video game epoch,' when video games soared in popularity, standardized achievement test scores of American children have remained largely static. The video game epoch has ushered in neither a wave of intellectually deficient and academically challenged children, nor a wave of unusually proficient children. This does not mean that the impact of video games on academics is necessarily null, however. As the Pew Research Center has noted (2012), video games are part of an increasingly technological period in society, and mastering this technology is going to be necessary for future success. It remains unclear whether video games are going to be a panacea for society as some have suggested (McGonigal, 2011). It is nice to think that this might be the case. But given the degree to which new technology tends to elicit extreme predictions of both dire harm and great success, it may take time before we fully come to understand the influence of video games on our society. In the meantime, as emphasized earlier, the research on both positive and negative effects of video games on academic achievement remains controversial and scholars are recommended to remain as conservative as possible when discussing video game effects to policy makers and the general public.

Computer Mediated Communication

Abstract

Computer-mediated communication (CMC) involves sending messages through computer networks such as the Internet. Research on the social impacts of text-based CMC began with a cues-filtered-out perspective, highlighting the loss of social information due to the absence of face-to-face, nonverbal cues. More recent theories focus on how message senders exploit the CMC medium in order to create messages and relationships actively. A sender-receiver-message-channel-feedback model of communication reveals how CMC affects social dynamics.

Communication technologies have potentially altered the way human beings share information with one another. The ability to communicate by sending and receiving text information has been more readily available in recent history. Just as the Pony Express, the telegraph and the telephone enabled individuals to communicate across great distance, new communication technologies have again reinvented the available means of communication. Electronic communication technologies utilizing computers have refamiliarized our society with text-driven means of connecting with each other. Yet, despite the changes associated with historical text-based interpersonal media such as mail and phone, the rapid speed and other unique affordances of the Internet has sparked considerable interest in how *computer-mediated communication* (CMC) differs from traditional communication.

The earliest research on CMC focused on the effects of new technology related to task performance outcomes. In the 1980s and 1990s, CMC consisted of electronic email and computer conferencing, chats, and electronic bulletin board systems hosting online forums. Research addressed the effects of those text-based communication systems not only on tasks, but also how the social dynamics and effects of the technology on users affected tasks or group performance. Today, with a greater variety of social media and expanded roles for their application, communication technology now plays an integral role in how people interact with one another across myriad types of social relationships.

Communication technologies available today have increased the frequency, ubiquity, and impact of CMC. Individuals often work and interact with others via computers on a daily basis. People may access CMC through their mobile devices as well as computers. More complex and crowd-based systems exist today to provide new means of digital collaboration and online sharing. Social media technologies, such as Facebook and Twitter, provide highly accessible means of CMC by relating the content to the people we know. In addition to new enablement and accessibility, communication patterns today blend the use of offline and online channels across most of our personal and professional relationships (Ramirez and Zhang, 2007).

Despite the mass proliferation and integration of CMC into our lives today, the delineation between CMC and other forms of communication remains useful and necessary in order to understand how technology affects communication processes. Even though CMC now hosts more multimodal channels in terms of photos, videos, and immersive graphical environments, text-based communication remains as a mainstay of how individuals exchange messages. Research developed on the basis of older text-based forms of CMC should continue to apply. As we develop an understanding of how CMC can affect communicators we can posit new questions as newer communication technologies such as Web 2.0 continue to expand the range of CMC. With that in mind, this article reviews several theoretical perspectives on CMC by focusing on the effects of CMC on those who use it, following the perspective of a basic communication model.

CMC: A Communication Perspective

A basic model of communication aids in identifying the impact of CMC, the central components of which include senders, receivers, messages, feedback, and communication channel (see for review Walther, 1996). S*enders* initiate the exchange of information by articulating intentions into information to be conveyed to others. The *message* contains the information symbols representing the information to be exchanged. Senders deliver messages by using a *communication channel*, the vehicle that carries the message. Such vehicles include face-to-face communication, telephone, teleconference, Facebook posts, and electronic chats, among others. *Receivers* interpret the message and often provide a return message in the form of *feedback*. This feedback reverses the role of the senders and receivers as the cycle continues iteratively until the termination of the communication event.

In addition to the capabilities of the CMC channel, CMC also occurs across different contexts. For example, Facebook's social context alters how users may interpret and construct messages relative to email or other systems. When a Facebook user posts a status update, members of this person's social network may read the message in light of past interactions with that user. On the other hand, messages exchanged on a company or organization's office chat system likely result in a different interpretive framework. Employees may experience

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95090-6

more reluctance in sharing social activities outside of the workplace on company websites as opposed to their friends and family via Facebook.

New communication technologies challenge existing theoretical perspectives. Early views of CMC focused on comparing the ability of the communication channel to those in face-to-face communication and/or other forms of CMC. Theoretical developments that followed offered a different view of CMC. Instead of focusing on the limiting constraints of the communication channel, these developments focused on how users can adapt to CMC to convey messages. We begin with an overview of the earlier theoretical view of CMC based on channel characteristics.

Cues-Filtered-Out Theories

Culnan and Markus (1987) first described a class of CMC theories as adopting a *cues-filtered-out* approach. The major contention in these theories maintains that CMC constraints the symbol systems that are available in the communication process, and thereby limits the meaning that users are able to exchange. Because CMC is primarily text-based, it lacks nonverbal cues. These theories assumed a relationship between the restricted cues that the channels offered and a commensurate restriction in senders' abilities to convey certain kinds of messages. There was less focus on the senders and receivers in terms of their potential adaptation of messages to alternative channels. Several particular theories typify the cues-filtered-out perspective.

Social Presence Theory

The first theory applied to CMC that reflected a cues-filtered-out perspective is social presence theory. Short et al. (1976) conceptualized that various communication systems differ in the availability of cue systems. Short et al. also claimed that the decrease of cues corresponded to a decrease in social presence between communicators. Although the theory originally focused on telecommunication systems, it was applied to CMC in the 1980s and 1990s.

The restriction of cue systems was suggested to impact the degree of social information a system could convey. Therefore, information about individuals' character and personality, and their interpersonal warmth and ease would be unlikely to be exchanged effectively without nonverbal cues, from a social presence perspective.

Media Richness Theory

Social information differs from more instrumental forms of information, for which certain other cues-filtered-out theories, media richness theory in particular (Daft and Lengel, 1984, 1986), suggest that "leaner" media (without nonverbal cues) may be more efficient. For instance, CMC may suffice when one person needs to tell another person the date for an event. On the other hand, if an individual wished to get to know another person's character or personality – characteristics which nonverbal cues might more efficiently convey – social presence and media richness theories suggest that CMC would denude the quality of information due to the lack of nonverbal cues to express socioemotional content.

Media richness theory focused on how organizations can utilize different types of communication channels to deal with decision-making contexts. Daft and Lengel (1984) attempted to provide a model for how different communication channels (e.g., memos, letters, chats, telephone conversations, and face-to-face interactions) rank in their abilities to reduce the equivocality managers experience during decision making. Equivocality refers to the ambiguity that arises from the presence of multiple, possibly conflicting interpretations. For example, a decision regarding whether a new policy should be adopted should evoke high equivocality. Such a context involves discussions among various managers and different interpretations regarding the consequences of the policy implementation.

These researchers contended that the ability of the communication channel to manage equivocality depended on information richness, which is comprised of (1) feedback speed or the rapidity of feedback, (2) multiple cues or the number of cues supported by the communication system, (3) language variety or the range of meaning that can be conveyed with language, and (4) personal focus or the ability of the communication to convey personal feelings and emotions (Daft et al., 1987). According to the media richness view, face-to-face communication would rank as the richest channel whereas other forms of mediated communication would be leaner (Daft et al., 1987). Face-to-face communication contains fast feedback, the greatest number of cues, the use of natural language, and the ability to adapt to individuals. On the other hand, CMC, such as chats and emails, would rank lower due to the lack of some richness criteria. It is regarded as a leaner group of channels.

Media richness theory argued that the best communication performance occurs as a function of matching the equivocality of the communication task to the richness of the communication channel. Specifically, high equivocality would require high information richness, and vice versa. For instance, managers attempting to make a policy decision require discussion and interpretation among multiple perspectives, thus face-to-face communication would be ideal. Alternatively, sharing accounting information or other objective data does not elicit a high degree of equivocality, meaning that a lean channel such as email would actually be more ideal in this context.

Empirical Findings

Both social presence theory and media richness theory provide a fairly intuitive understanding of CMC. The simplicity of treating different CMC categorically based on the absence of nonverbal cues is transparent and simple. Perhaps due to such an appeal, numerous investigations followed a cues-filtered-out approach in both organizational and interpersonal contexts. However, the empirical support has been generally mixed.

Social presence theory has received numerous critiques and challenges for the oversimplification explanation of CMC in a social context (Lea and Spears, 1992; Walther, 1992). In short, these critiques centered on challenging the assumptions and artifacts present in social presence work. Media richness

theory has also been challenged in from multiple angles. First, the original study did not directly test the theoretical proposition laid out by its authors. The empirical support used to substantiate the theory's formulation involved asking managers what communication channel they would select in a number of communication contexts that differed in equivocality. Daft et al. (1987) found a positive correlation between how well the managers selected the communication channel and the manager's actual performance evaluations. This correlation did not test the theoretical proposition that using various communication channels resulted in the best decision-making outcome, given situations that vary in equivocality. Dennis and Kinney (1998) experimentally tested media richness theory and failed to find supporting evidence. These researchers found that richness led to differences in the time that it would take to complete a task. However, richness did not affect decision quality. In short, the critiques and contradictory evidence limit the viability of the cues-filtered-out approach to understanding CMC.

Despite the critiques and problems associated with cues-filtered-out approaches, this view of CMC continues to perpetuate in recent studies of new media (see for review Walther, 2011). Adopting a cues-filtered-out approach often hinders the advances possible in the study of CMC. Fortunately, alternative theoretical views focus on how CMC integrates factors beyond those in the communication channel alone.

Social Identity Model of Deindividuation Effects

The social identity model of deindividuation effects, or *SIDE* model (Lea and Spears, 1992), shares some similarities with the other cues-filter-out theories. Specifically, SIDE also assumes that the absence of nonverbal cues limits the transmission of interpersonal information online. However, unlike other cues-filtered-out approaches, the SIDE offers a mechanism for online communication based on visual anonymity and social identification. Visual anonymity occurs when communicators utilize text-based communication where no visual information about each other is available. Under such a condition, communicators deindividuate and lose a sense of self-awareness. If they identify themselves with a salient social group, they will likely follow the behaviors of that social group.

The following scenario exemplifies a scenario for how SIDE may function in CMC. Assume that a college student reads and writes responses on a political forum. If the forum is text-based, the student should remain visually anonymous to others on the forum, as well as others to the student. The student is able to garner information about others on the forum and realizes that some of the forum participants are also students at the same university. If the student identifies with the in-group of students from the same university, he or she should orient toward the behavior of those from the same institution (e.g., evaluate them as more attractive, follow the recommendations advocated). On the other hand, if the student realizes that some of the other contributors on the same forum are from a rival institution, he or she may regard these people as out-group members. The student is likely to evaluate these out-group members as less attractive and be less likely to follow any recommendations advocated by those members.

The SIDE model's parsimonious explanation of visually anonymous CMC led to a wide following. The theory has even been applied to understand the effect of CMC in interpersonal contexts: In the case of visually anonymous romantic partners who may have met online, SIDE offers an interesting interpretation for their relational development. An application of the SIDE suggests that romantic communication and attraction toward partners result due to the social identification they feel toward salient group identities. According to SIDE, the attraction does not develop out of interpersonal processes but group identification processes alone (Lea and Spears, 1995).

Taken together, the cues-filtered out approaches to CMC provide a limited understanding of how people communicate. The primary assumption that text-based communication can only convey a certain quantity or form of meaning ignores any possibilities of relational development or transformative properties using CMC. In the case of SIDE, the prediction that social identification with group members would lead to adherence to group behavior also assumed that visual anonymity and text-based communication restrict or discourage users from conveying personal and interpersonal information. The next few of theoretical perspectives focus more on the interpersonal capabilities of CMC. In particular, these perspectives emphasize communicators' ability to utilize CMC in such a way as to provide meaning, to detect and foster personal impressions, and develop relational communication that approximates, or even exceeds, the level of relational regard that is typical in face-to-face communication.

Theories of Interpersonal Adaptation

A fundamental difference between cues-filtered-out approaches and theories described below can be understood from the communication model. Cues-filtered-out approaches focus on the channel primarily, with the exception of SIDE which also focuses on receivers' social identification. Instead, the theoretical frameworks of interpersonal adaptation and exploitation of media posit an understanding of CMC through all components of the communication model, raising in prominence the role of the sender and the sender's active creation of messages and channels. This approach to understanding CMC paints a picture of how communicators can take advantage of all communication elements to share meaning.

Social Information Processing Theory

The social information processing (SIP) theory (Walther, 1992) assumes that individuals aim to develop interpersonal impressions and relations with others. It proposes that when the communication channel limits the cues available to communicators, as is the case using text-based CMC, individuals will utilize the available cues in that channel to share their desired meaning. In particular, communicators primarily utilize the content of the written language (e.g., the choice and style of words) to encode and decode information from others.

In addition to CMC adaptation from a sender's standpoint, SIP supposes that the CMC channel alters the rate of social information exchange compared to face-to-face communication. In other words, to develop to the same level of relationship, communicators who use CMC would require more time than those in face-to-face communication. This rate difference originates from the diminished information available in text-based CMC as opposed to face-to-face communication. Even as senders encode messages by adapting to the cues and meaning available in CMC, the communication takes more time to accrue the same meaning as those in face-to-face communication. However, it is important to note that the rate difference does not equate to a superiority or inferiority of CMC when compared to the face-to-face counterpart. Instead, social information simply needs more time to accumulate and render effects on relationships in CMC.

The Hyperpersonal Model of CMC

The hyperpersonal model of CMC (Walther, 1996) takes a step beyond SIP theory. Specifically, the hyperpersonal model contends that CMC may aid in the development of interpersonal relationships that even surpass those in face-to-face communication. Such a process entails a series of theoretical propositions that relate to (1) how receivers may process CMC information, (2) how senders may encode messages, (3) characteristics of the communication channel, and (4) feedback. These propositions coalesce to describe a CMC process that involves all components of the communication model.

Receiver Effects

A receiver may experience exaggerated perceptions of the message sender in CMC. Since a receiver does not have the cues present in face-to-face communication, the receiver has to fill the void by creating impressions regarding the sender. When initial cues lead to positive first impression, impression development may then involve idealization, where the receiver bestows characteristics about the sender preferentially. This articulation originated from the notion of social identification to group identity in SIDE theory. Newer accounts of the hyperpersonal model suggests that individual stereotypes, not just those based on common social categories, may also activate heightened receiver impressions (Walther, 2006).

Sender Effects

With a text-based CMC in mind, communicators can selectively present aspects of themselves online. As a result, they can manage which aspects of themselves to present to others, with an underlying goal to create a favorable impression in the other communication partner. Of course, individuals can choose to disclose negative personal information; however, the lack of nonverbal cues in CMC actually minimizes the nonverbal behavior that might damage positive interpersonal impressions (e.g., poor eye contact, body postures) in face-to-face communication. As a result, CMC senders can more easily select aspect of themselves to present to their partners to elicit favorable responses.

Channel

Not only can senders selectively self-present, their ability to do so is enhanced by the communication channel. Several aspects of CMC facilitate message construction. For instance, in the case of asynchronous CMC, both the sender and the receiver can utilize time to construct the message and feedback. Unlike face-to-face communication where the feedback between communicators is more immediate, a CMC sender and a CMC receiver have time to write the message, edit that message, or even delete and rewrite the message. The use of time and editing leads to more positive and affectionate messages (see for review Walther, 2011).

Feedback

According to the former three components of the hyperpersonal model, the sender may selectively self-present to garner positive impressions, the receiver may idealize the sender, while both the sender and the receiver may capitalize on the CMC channel to construct favorable messages. Based on these enhancements, the feedback system created between the sender and the receiver should contribute to a continuous elevation of positive impression as they communicate with each other. In other words, the feedback system in CMC should enhance the interpersonal dynamics at play and intensify the effects iteratively over time.

A synthesis of all four hyperpersonal components illustrates a communication dynamic where the positive impressions of the CMC communicators intensify over time. The model points the possibility where such intensification may exceed those experienced in face-to-face communication. Both SIP theory and the hyperpersonal model challenge the limited views provided by the cues-filtered-out approaches to CMC. Moreover, the theories of adaptation of exploitation of media paint CMC as an interactional landscape where users adapt and appropriate all available means in the communication process to reach affinity goals. Although the domain of these theories resides primarily in the interpersonal context, the theories' application and interpretation suggest that communication should be understood from the communicator's standpoint rather than the technology or the channel.

Online Information Evaluation

Warranting

In addition to cyclical communication processes posited by theories of interpersonal adaptation and exploitation of media, some recent theoretical concepts examine how individuals may make sense of information they receive online. Online communication may involve the information individuals disclose to each other. Individuals often evaluate the validity of information about another person online, also known as warranting (Walther and Parks, 2002). The communication technology today provides quick access to information. Online users also have access to a lot of information about others. For example, online users may share a lot of personal information on their online dating profiles including interests, religious views, hobbies, among others. The warranting idea suggests that information presented online may lead to a suspicion of

possible distortions through selective self-presentation, such as the sender effect specified by the hyperpersonal model. For example, information on dating websites may show both distorted physical (weight/height) and psychological (hobbies) characteristics. The warranting concept argues that such type of distortion is less likely to occur when two communicators have access to each other's social network. Specifically, when one communication partner's social circle is available, one partner can hold the other responsible for the content of the self-disclosure and verify that content. Based on warranting, information that is more likely to relate to a communication partner's social network is less likely to be seen as distorted. Warranting is useful in predicting how communicators may judge the social information provided by others online.

Participatory Websites

The CMC available today has dramatically changed from the early text-based forms. Most online communication occurs via websites that feature some social information from other users. These types of participatory websites, known as Web 2.0, complicate the theoretical concepts for understanding the underlying communication dynamics at play. Moreover, these social websites juxtapose messages from various sources. An original author of some Web content may receive comments and evaluation from other users regarding that content. From a communication perspective, information regarding the sender, receiver, message, feedback, and context may blend together in a single webpage. The additional user-generated content may serve to modify how other readers may evaluate the content advocated by the original author, the original author as a source, others who comment on the source, as well as the content of the comments advocated by others.

This following example illustrates the complexity of understanding Web 2.0. Suppose that a product reviewer posts a positive product review on Amazon.com. Assuming that the review was meant to advocate to other readers for purchasing a particular product, other readers may compose comments on the review. If other readers write positive comments regarding the review, then those who read the original review and corresponding comments may regard the product as positive overall. However, if the review received negative comments that do not support what the review advocates, readers of the reviews and the comments that follow have to make sense of both positive and negative information. To complicate matter even more, Amazon.com reviewers and commenters may be rated in terms of how helpful they are. These types of information juxtapose against one another as the reader may review them on a single website.

Walther and Jang (2012) offered a conceptual foundation for defining the various sources available on Web 2.0 sites. They proposed four elements including proprietor content, user-generated content, deliberate aggregate user representations, and incidental aggregate user representations.

Proprietor Content

Proprietor content relates to the message composed by the primary author or the proprietor of a webpage. The proprietor has controls over message that he or she composes. The proprietor may edit that message (e.g., deleting a Facebook post). The message may include videos, text, and/or pictures. Furthermore, these forms of messages may operate in combination. A Facebook picture may accompany the written post in text. Examples of proprietor content include YouTube videos, Amazon.com reviews, Facebook profiles, among others.

User-Generated Content

User-generated content (UGC) relates to the messages that other users contribute. This content does not originate from the proprietor, but instead, from those who compose content in response to the proprietor content. UGC differentiates Web 2.0 from traditional websites. Unlike traditional websites (e.g., a webpage that does not allow users to write comments), Web 2.0 displays UGC alongside the proprietor content. Examples of UGC include comments responding to a Facebook post, comments on product reviews (comments written in response to an online news article).

Aggregated User Representations

Web 2.0 systems also allow users to leave evaluations of others' content. These evaluations may relate to proprietor content, as well as UGC. Web 2.0 systems often encourage users to rate or vote on the content produced by others. Then, the system aggregates the ratings for others to view. The aggregated ratings take the form of some statistics or figures. Examples of these representations include the number of stars, total votes, usefulness votes, helpfulness ratios, among others. To delineate among the different types of user representations, there are *deliberate and incidental* aggregate user representations.

Deliberate aggregate user representations include responses generated from directly requesting those responses from users. For instance, after displaying an opinion from a user, the Web 2.0 system may solicit readers to rate if that opinion was useful or not useful (e.g., 1 to 5 stars). An example of deliberate representation may include ratings of review helpfulness. Amazon.com displays the accumulated ratings of helpfulness in the form of a ratio (e.g., 40 out of 41 people found the review helpful).

In contrast, incidental aggregate user representations include information captured by Web 2.0 systems. In particular, these representations do not reflect behaviors that users would like to express, but instead, they are computed by the Web 2.0 system and displayed with other information. Examples of these representations include the number of Facebook friends, number of views on a YouTube video, the timestamp of a particular comment or review, among others. These representations offer a unique persuasive quality in that online users have no control over them. As a result, they may serve to aid certain aspects of self-presentations from a warranting perspective.

Participatory Websites and Juxtaposition among Sources

Participatory websites create unique theoretical challenges for CMC. Although the theoretical terms expressed previously aid in defining the various conceptual components involved in Web 2.0, they do not offer a set of theoretical

propositions regarding the relationships among the concepts. From a communication perspective, the model elements of the sender, receiver, message, context, and feedback also offer little explanatory utility as these components mix to serve multiple roles in Web 2.0. For instance, a message proprietor may respond to UGC and create a conversation between a proprietor and a commenter. At the same time, other users contribute to this dynamic through rating both the proprietor content and/or the UGC. When the Web 2.0 system displays all these contents simultaneously, how do other readers process that information and continue in the participatory process by adding or rating the existing content? What if more than one commenter is involved? This question typifies the theoretical challenge in the study of CMC as new technology enable online communicators to interact at such a convergent level across multiple information sources and ratings.

Summary and Future Direction

The current review began with an explanation of the communication perspective and elements in the communication model. With this perspective in mind, we reviewed a few of the theories involved in understanding CMC. The cues-filtered-out approaches assumed CMC's lack of nonverbal cues limited communication. On the other hand, theories of interpersonal adaption and exploitation of media posit a more interactive process that may match and/or exceed face to face. Finally, the conceptual framework for understanding participatory websites provides a glimpse of the complexity and challenge of theory development. As research incrementally increases our understanding of CMC, technology is also on the forefront of altering the landscape of digital interaction. Web 2.0 site continue to modify both interface as well as the type of information available to users.

This article is a revision of the previous edition article by W.J. van der Linden, volume 4, pp. 2477–2480, © 2001, Elsevier Ltd.

Abstract

This article starts with a brief introduction to the area of computerized test construction. In the first section, the problem is formally stated as an optimization problem, with an objective function, for example, that maximizes the amount of information in the test or minimizes the amount of items in a test. In the second section, an overview is given of the methods that are available for computerized test construction. In sections computerized construction of linear test forms, construction of computerized adaptive tests, and construction of multistage tests, some specific issues related to the three most important test forms are discussed. The article ends with a discussion on one of the recent issues in computerized test construction, the problem of uncertainty in some of the parameters during optimization.

Test Construction as a Combinatorial Optimization Problem

Combinatorial optimization problems are those where mathematical techniques are applied to find optimal solutions within a finite set of possible solutions. The set of possible solutions is generally defined by a set of restrictions, and the set is too large for exhaustive search. A well-known example is the knapsack problem, where the value of the goods carried in the knapsack has to be maximized, while the weight of the goods that can be carried is limited. A second example is the traveling salesman problem, where the total traveling distance has to be minimized while each client is visited exactly once. The computerized test construction problem is also an example of a combinatorial optimization problem. From a finite item bank, a group of items has to be selected that is optimal with respect to the goal of testing, while the resulting test has to meet all specifications.

To formulate the test construction problem as a combinatorial optimization problem, a decision variable x_i is introduced that denotes whether item $i = 1,\ldots, I$, is selected ($x_i = 1$) or not ($x_i = 0$), an objective function has to be formulated to be optimized, and restrictions have to be identified.

Objective Functions in Computerized Test Construction

An objective function in test construction has to reflect the goal of testing that has been set in the first step of Birnbaum's approach. How to translate the objectives for test construction to psychometric properties depends on the measurement framework that is used. When the classical test theory (CTT) is applied to relate the responses of the candidate to a score representing the ability (Lord and Novick, 1968), the goals of testing are generally formulated in terms of reliability (approximated by Cronbach's alpha) or predictive validity of the test. Maximizing the reliability can be formulated in terms of the decision variable x_i as

$$\max \frac{n}{n-1}\left[1-\frac{\sum_{i=1}^{I}\sigma_i^2 x_i}{\left(\sum_{i=1}^{I}\sigma_i\rho_{iX}x_i\right)^2}\right], \qquad [1]$$

where n denotes the test length, σ_i the item variance, and ρ_{iX} the item discrimination. Maximizing the predictive validity can be formulated as

$$\max \frac{\sum_{i=1}^{I}\sigma_i\rho_{iY}x_i}{\sum_{i=1}^{I}\sigma_i\rho_{iX}x_i}, \qquad [2]$$

where ρ_{iY} is the item validity.

Within an item response theory (IRT) framework, the relationship between the responses of a candidate and the ability are modeled by an item response function, for example, the two-parameter logistic model (2PLM, Lord, 1980):

$$P_i(\theta) = \frac{e^{a_i(\theta-b_i)}}{1+e^{a_i(\theta-b_i)}}, \qquad [3]$$

where $P_i(\theta)$ denotes the probability that someone with ability θ will provide a correct answer to item i, and (a_i, b_i), also referred to as item parameters, denote the discrimination and the difficulty parameter of item i. Other examples of IRT models are the Rasch model, the three-parameter logistic model, or the normal ogive models (Lord, 1980). Within an IRT framework, the objective functions in test construction are generally formulated in terms of Fisher information. Fisher information has some favorable features when it comes to test construction. Fisher information for the whole test is equal to the sum of Fisher information of the items, and the inverse of Fisher information is asymptotically equal to the variance of the ability estimate. In other words, high information implies small uncertainty in the resulting scores. For the 2PLM, Fisher information for the whole test is given by

$$I(\theta) = \sum_{i=1}^{I}\frac{\partial P_i(\theta)/\partial\theta}{P_i(\theta)[1-P_i(\theta)]}x_i. \qquad [4]$$

This test information function (TIF) can be maximized for a single ability value or for a range of ability values, or different targets can be set for various values of the TIF.

For an overview of objective functions, both in a CTT and in an IRT framework, see van der Linden (2005, Chapter 5).

Restrictions in Computerized Test Construction

Restrictions in combinatorial optimization refer to specifications that have to be met for groups of items that are selected. In computerized test construction, three types of specifications can be distinguished: categorical, quantitative, and logical specification. Categorical specifications refer to item attributes, such as content, item type, or format, that categorize the items in different subsets. For each of these subsets, the number of items to be included in the test can be specified. Quantitative specifications refer to attributes like response times, word counts, or statistical attributes. The sum of the quantitative attributes of all items selected for the test, for example, the total word count, is restricted by these constraints. Logical specifications deal with relationships between items. Items that belong to an enemy set cannot be selected for the same test. Therefore, only one of the items from this subset can be selected. Van der Linden (2005, Chapter 3) presents an extensive overview of various types of constraints, and of its applications to test construction. All specifications can also be formulated in terms of the decision variables. A complete combinatorial optimization model for computerized test construction is formulated in the next section.

Computerized Test Construction Model

A very general model for computerized test construction can be formulated as

$$\max \sum_{i=1}^{I} I_i(\theta_j)x_i \quad \text{(objective function)} \qquad [5]$$

subject to

$$\sum_{i \in V_c} x_i \leq b_c \quad \forall c \quad \text{(categorical constraints)} \qquad [6]$$

$$\sum_{i=1}^{I} q_i x_i \leq b_q \quad \forall q \quad \text{(quantitative constraints)} \qquad [7]$$

$$\sum_{i \in V_l} x_i \leq b_l \quad \forall l \quad \text{(logical constraints)} \qquad [8]$$

$$\sum_{i=1}^{I} x_i = n, \qquad [9]$$

$$x_i \in \{0, 1\} \quad i = 1, \ldots, I \quad \text{(decision variables)}. \qquad [10]$$

Where I is the number of items in the bank, c, q, l are indices for the categorical, quantitative, and logical constraints, (b_c, b_q, b_l) denote the bounds for the constraints, and V_c and V_l denote sets of items affected by constraints c or l. The objective in this model is to maximize the TIF for ability level θ_j. This type of objective function is generally applied for mastery testing, where most information is needed around the cut-off point θ_j. Depending on the goals of testing, other objective functions can be applied.

Algorithms for Computerized Test Construction

Two classes of algorithms have been proposed for computerized test construction. First of all, mixed integer programming (MIP) solvers based on branch-and-bound algorithms can be applied. These algorithms guarantee that an optimal solution of the test construction problem is found, if one exists. If no solution to the test construction problem can be found, i.e., no test can be selected from the item bank that meets all the test specifications, these solvers can provide feedback on sets of constraints that together or by themselves cause the infeasibility problems (Huitzing et al., 2005). The commercial software package CPLEX (IBM, 2010) is one of the most powerful programs to solve test construction problems, but alternative solvers like the LpSolveAPI in the R-package are also available. Over the years, MIP solvers have proved to solve most computerized test construction problems within minutes or even seconds. Second, various heuristics for solving test construction problems have been proposed in the literature. These heuristics are often tailor-made for the test construction problem at hand. They are often easy to implement, but they approximate the optimal solution, so it cannot be guaranteed that the optimal test is constructed. Besides, finding the optimal settings of a heuristic might be rather time consuming. Some well-known heuristics for computerized test construction are the weighted deviation model (Stocking and Swanson, 1993), the normalized weighted average deviation heuristic (Luecht and Hirsch, 1992), network programming (Armstrong et al., 2005), simulated annealing (Veldkamp, 2002), genetic algorithms (Verschoor, 2007), and the MCMC (Markov Chain Monte Carlo)-based test assembly algorithm (Belov and Armstrong, 2005).

Computerized Construction of Linear Test Forms

Linear tests can be characterized as a fixed set of items presented in a fixed order. Paper-and-pencil tests are in this category, but they are also administered more and more often on a computer. The model in Eqns [5]–[10] can be applied to assemble a linear test form suitable for making mastery/nonmastery decisions around a cut-off point θ_j. If the goal of the test is to measure for a broader ability range, targets are generally formulated for Fisher information for these ability values, and the objective function for computerized test construction is to minimize the distance between the TIF and its target. Instead of minimizing the difference for all ability values, it often suffices to minimize the difference for a number of points θ_k, $k = 1, \ldots, K$, spread over the ability range of interest. This objective can be modeled as

$$\min_{k=1,\ldots,K} \left| \sum_{i=1}^{I} I_i(\theta_k)x_i - T(\theta_k) \right|, \qquad [11]$$

where $T(\theta_k)$ represents the target for Fisher information at θ_k. Boekkooi-Timminga and van der Linden (1989) developed a maximin model for this problem, in which a new variable γ is introduced, which serves as an upper bound for the

absolute difference between the TIF and the actual information function. In this way the optimization problem in Eqn [10] is rewritten as an MIP problem, and standard MIP solvers or heuristics can be applied:

$$\min y \qquad [12]$$

subject to

$$\sum_{i=1}^{I} I_i(\theta_k)x_i \leq T(\theta_k) + y \qquad [13]$$

$$\sum_{i=1}^{I} I_i(\theta_k)x_i \geq T(\theta_k) - y \qquad [14]$$

In many testing programs, more than one test has to be constructed. It could be that several parallel test forms have to be administered at the same time, that the test is administered periodically, or that the test is used in a quasiexperimental pre-posttest design (e.g., Cook and Campbell, 1979). To assemble multiple test forms concurrently, the test construction model in Eqns [5]–[10] is slightly modified by using decision variable x_{it} that indicate whether item i is selected ($x_{it} = 1$) for test t or not ($x_{it} = 0$), instead of decision variable x_i. When overlap between tests is prohibited or limited, the following logical constraint can be added to the model:

$$\sum_{t=1}^{T} x_{it} \leq n_i \quad i = 1, \ldots, I \qquad [15]$$

where n_i denotes the number of times item i can be selected concurrently. Since both the number of decision variables and the number of constraints grow linearly in the number of tests to be selected, 0–1 MIP algorithms might be very time consuming. Especially for the problem of concurrent construction of multiple partly overlapping tests, genetic algorithms and MCMC-based test assembly have demonstrated to be very efficient.

Construction of Computerized Adaptive Tests

Computerized adaptive tests (CATs) are individualized tests where the difficulty of the items is adapted to the ability of the candidate. In CAT, items are selected sequentially. After administration of each item, the ability of the candidate is estimated based on the responses he or she provided to the previous items. Then the item is selected and administered that maximizes Fisher information at the estimated ability level. The procedure is repeated until a stopping criterion, e.g., a fixed number of items or a minimum level of measurement precision, has been met. The first item can be selected randomly, or based on an initial guess of the ability level of the candidate. A major advantage of CAT is that test length is reduced up to 40%, and tests can be administered individually when a candidate prefers. For a thorough introduction to CAT, the reader is referred to Wainer (2000).

In case a set of specifications has to be met, the shadow test approach (van der Linden, 2005, Chapter 9) could be applied. This two-stage procedure for item selection constructs a 'shadow test' in every iteration of CAT from which the most informative item is chosen to be administered. The 'shadow test' consists of a group of most informative not-administered items which in combination with the items that have been administered already fulfill the requirements of the specifications. The following model can be applied to construct a 'shadow test' for selecting the g-th item:

$$\max \sum_{i=1}^{I} I_i(\hat{\theta}_{g-1})x_i \qquad [16]$$

subject to

$$\sum_{i=1}^{I} x_i = n \quad \text{(test length)} \qquad [17]$$

$$\sum_{i \in V_c} x_i \leq b_c \quad \forall c \quad \text{(categorical constraints)} \qquad [18]$$

$$\sum_{i=1}^{I} q_i x_i \leq b_q \quad \forall q \quad \text{(quantitative constraints)} \qquad [19]$$

$$\sum_{i \in V_l} x_i \leq b_l \quad \forall l \quad \text{(logical constraints)} \qquad [20]$$

$$\sum_{i \in S_{g-1}} x_i = g - 1 \quad \text{(previous items)} \qquad [21]$$

$$x_i \in \{0, 1\} \quad i = 1, \ldots, I \quad \text{(decision variables)}, \qquad [22]$$

where $\hat{\theta}_{g-1}$ denotes the ability to estimate after administering $(g-1)$ items and S_{g-1} denotes the set of items that has been administered so far. By application of this model, the same kind of specifications can be applied in CAT as in linear testing. An alternative procedure for dealing with test specification in CAT would be to apply the weighted deviation model (Stocking and Swanson, 1993).

In CAT, some items are selected more often than others, since they are more informative. As a result, their content might be compromised. To prevent these security issues and to increase item bank usage, exposure control methods can be applied. These methods prevent the selection of popular items either by conducting a chance experiment after selection of each item where the probabilities of selection are inversely related to the popularity (Sympson and Hetter, 1985) or by temporarily excluding them when they are administered too often (van der Linden and Veldkamp, 2004).

Construction of Multistage Tests

Multistage testing is a hybrid of linear testing and CAT. Instead of administering a single item, a small linear test, also referred to as a module (Luecht and Nungester, 1998), is administered before the ability estimate is updated. After estimating the ability, the candidate is routed to an easier or more difficult module. A multistage test design typically consists of several stages in which a module is administered. Each path a candidate might follow through the test has to meet all test specifications. An example of a multistage test design with three stages, six modules, and four paths is given in **Figure 1**.

To develop a multistage test, several decisions have to be made about the number of stages, routing rules, number of items in a module, and psychometric properties of the modules

Figure 1 Multistage test design.

(Zenisky et al., 2010). The model for constructing the modules is equivalent to the model for the construction of a number of (non)overlapping small linear tests, while an additional set of specifications for each combination of tests that belong to a path has to be met:

$$\sum_{t \in P_p} \sum_{i \in V_c} x_{it} \leq b_c \quad \forall c, \forall p, \qquad [23]$$

$$\sum_{t \in P_p} \sum_{i=1}^{I} q_i x_{it} \leq b_q \quad \forall q, \forall p, \qquad [24]$$

$$\sum_{p \in P_p} \sum_{i \in V_l} x_{it} \leq b_l \quad \forall l, \forall p, \qquad [25]$$

where p is an index denoting various paths in the design. Zenisky et al. (2010) pointed out that it should be considered whether specifications should be achieved within stages or across the whole test. Meeting the constraints over the whole test provides greater flexibility, at the cost of imposing the additional constraints in Eqns [23]–[25] to the model.

Robust Computerized Test Construction

In all these test construction models, it is assumed that the item parameters and item attributes are known. Fixed values are used to compute the contribution of each item to both the objective function and the constraints. Unfortunately, many of them have been estimated. IRT parameters, for example, have been estimated when the items were pretested, and they do have uncertainty in them that is reflected by the standard error of estimation. This uncertainty is generally not taken into account. Hambleton and Jones (1994) already warned about the consequences. When the objective of test construction is to maximize the information in the test, and the uncertainty in the item parameters is not taken into account, the amount of information in the resulting test will be seriously overestimated, especially when the item parameters have been estimated with small sample sizes or when relatively few items are selected. Since the amount of information in the test is inversely related to the variance of the ability estimate, this implies that overestimation of the information in the test has serious consequences for the measurement precision and the reliability of the test.

De Jong et al. (2009) proposed a robust test construction algorithm to deal with these problems. Inspired by the work of Soyster (1973), they subtracted one time the standard of estimation from the parameter estimates, and formulated a robust test construction model as

$$\max \sum_{i=1}^{I} I_i(\theta_j, \zeta) x_i \quad \text{(objective function)} \qquad [26]$$

where ζ denotes the level of uncertainty, and

$$I_i(\theta_j, \zeta) = I_i(\theta_j) - SE(I_i(\theta_j)). \qquad [27]$$

For small values of the standard error of estimation, the results for the test construction problem in Eqns [5]–[10] and its robust counterpart are almost the same, but for large values, a considerable difference will be obtained.

Computers: Impact on the Social Sciences

Gerd Gigerenzer, Max Planck Institute for Human Development, Berlin, Germany

Abstract

The social organization of labor in the nineteenth century served as the model for Babbage's first computers. In the second half of the twentieth century, when working computers were finally constructed and invaded the offices of social scientists, they turned into theories of mind. This mutual inspiration first changed the meaning of calculation and then led to a new understanding of thought as computation based on hierarchically organized subroutines. The computer as a research tool has changed the social sciences in a fundamental way, from enabling large-scale simulations of cognitive and social systems to allowing mindless and mechanical use of statistics.

A new social organization of the workplace, the large-scale division of labor in manufacturing, served as the original model for Charles Babbage's computers. Today's computer metaphor of mind still reflects this origin: it pictures cognitive processes – from reasoning to creativity – as a hierarchical organization of subroutines. The two different uses of computers – for calculation (number processing) and computation (symbol processing, as in simulation) – vary markedly among scientific disciplines. The computer has revolutionized our conception of mind and society in the sense of a re-volution to the Enlightenment's combinatorial view of thought and Adam Smith's ideal of the division of labor.

Following the advent of writing and of the printing press, the invention of the computer has been described as the third information revolution. Computers transformed our world, in reality and fiction: from the World Wide Web to the vision of machines that will eventually surpass humans in intelligence and even replace us by self-replicating computers divorced from biological evolution. This revolution was difficult to foretell. Howard Aiken, the Harvard mathematician and builder of the Mark I calculator, recalled: "Originally one thought that if there were a half dozen large computers in this country, hidden away in research laboratories, this would take care of all requirements we had throughout the country." This prediction was based on the false assumption that computers are there to solve scientific problems only. Back in the 1960s, electrical engineer Douglas Carl Engelbart had already designed the first interactive computer tools, including the mouse, on-screen editing, screen windows, hypertext, and electronic mail. However, at this time, human–computer interaction still seemed a pipe dream – computers were for processing punched cards, not for interacting with humans. The impact computers had on society and science was difficult to imagine, and its future impact is equally impossible to envision.

What remains clear is that its impact is bidirectional: computers and humans coevolve. This is illustrated by the work of Charles Babbage (1791–1871), the English mathematician often credited with the invention of the digital computer.

The Computer as a Factory of Workers

Babbage's Analytical Engine, a mechanical computer, was inspired by and modeled on a new social organization of work: the large-scale division of labor, as evidenced in the English machine tool industry and in the French government's manufacturing of logarithmic and trigonometric tables for the new decimal system in the 1790s. Inspired by Adam Smith's praise of the division of labor, French engineer Gaspard de Prony organized the project in a hierarchy of tasks. At the top were a handful of first-rank mathematicians who devised the formulae, including Adrien Legendre and Lazare Carnot; in the middle, seven or eight persons trained in analysis; and at the bottom, 70 or 80 unskilled persons who performed millions of additions and subtractions.

Once it was shown that elaborate calculations could be carried out by an assemblage of unskilled workers – rather than by a genius such as Gauss – each knowing very little about the larger computation, Babbage was able to conceive of replacing these workers with machinery. Babbage, an enthusiastic 'factory tourist,' explicitly referred to this division of mental labor as the inspiration for his mechanical computer and adopted terms from the textile industry such as 'mill' and 'store' to talk about its parts. Similarly, he borrowed the use of punched cards from the Jacquard loom, the programmable weaving machines that used removable cards to weave different patterns. Thus, in the beginning was a new social system of work, and the computer was created in its image.

The Hierarchical Organization of the Mind

Babbage's Analytical Engine was never completed. Around 1890, the first 'digital calculators' were manufactured, so called because they represented numbers by cogged wheels whose positions corresponded to the *digits* in the numbers denoted. (An abacus was still cheaper and faster.) Digital computers competed with analog computers, in which continuous quantities, such as electrical potential or mechanical motion (slide rules) were used instead of discrete (e.g., on/off) states. Until the first third of the twentieth century, digital calculators remained essentially mechanical. In the late 1930s, electromechanical relay switches started replacing gears and cogs in calculators. The electronic computer based on vacuum tubes and containing no movable parts appeared during World War II and was invented in three separate locations: in Germany for airplane design, in the USA for calculating artillery tables, and in the UK for breaking German secret codes. Vacuum tubes

were eventually replaced by transistors and then by silicon chips, which allowed the transition from large mainframes to minicomputers. The first personal computers – complete with keyboard, screen, disk drive, and software – were marketed by Apple in 1977 and by IBM in 1981.

Through these dramatic improvements in hardware and speed, Smith's ideal of the division of labor became the basis for a fresh understanding of the human mind. Herbert Simon and Allan Newell proposed that human thought and problem solving were to be understood as a hierarchical organization of processes, with subroutines, stores, and intermediate goal states that decomposed a complex problem into simple tasks. In fact, a social system rather than a computer performed the trial run for the Logic Theorist, their first computer program. Simon's wife, children, and graduate students were assembled in a room where each of them became a subroutine of the program, handling and storing information. This social design resembled that of the nineteenth-century French *bureaux de calculs* and the Manhattan project, where calculations were performed by an unskilled, poorly paid workforce of mostly women. This vision of intelligence resulting from a crowd of ignorant elements made its way into cognitive theories. For instance, Marvin Minsky, one of the founders of artificial intelligence, regarded the mind as a society of dumb agents, collectively creating true intelligence. In the same spirit, anthropologists began to use computer analogies to understand how social groups make decisions, such as how the crew on a large ship solves the problem of navigation by storing, processing, and exchanging information. Thus, the direction of the analogy was eventually reversed: originally, the computer was modeled on a new social system of work; today, social systems of work are modeled on the computer.

From Calculation to Computation

A crucial insight occurred when the early generation of computer designers realized that a computer could be used not only for calculation but more generally for symbol processing. The switch positions inside the machine could take on other meanings than numbers; they could also stand for symbols representing concepts. This insight fueled the view of *cognition as computation*, that is, symbol manipulation. A computer that merely performed complex calculations would not have suggested itself as a model of human thought. During the Enlightenment, proficient calculation was indeed seen as the essence of intelligence and even moral sentiment, but after the large-scale division of labor introduced around 1800, prodigious mental reckoning had become the mark of the idiot savant rather than the genius.

The notion of computation led to two questions: Can computers think? Is human thought computation? To avoid endless philosophical debate on exactly how to define the first question, Alan Turing (1912–54) suggested the 'imitation game,' now known as the Turing test: A human interrogator must distinguish between a computer and a human subject based on their replies to the interrogator's questions. In a series of such experiments, a computer's ability to think could be quantified as the proportion of interrogators who misidentify the machine as the human subject. Turing asked whether the computer is like a mind: whether it thinks and has free will, and whether one can teach machines to become intelligent using the same psychological principles used to teach children. Those who focused on the second question – Is the mind like a computer? – saw the analogy point in the other direction. For instance, some tried to teach children using the same principles that had worked for computers. This analogy of the mind as computer triggered the cognitive revolution in psychology during the 1960s and 1970s.

The 'physical symbol system' hypothesis proposed by Simon and other researchers in artificial intelligence assumes that human cognition *is* computation in the sense of symbol manipulation. According to this view, symbols represent the external world; thought consists of expanding, disassembling, and reforming their structures, and intelligence is nothing more than the ability to process them. Information processing became the key to understanding human thought, while the tools of programming provided the mechanisms of thought: production systems, subroutines, recursion, iteration statements, local naming, interpreters, and so on. This view was not easily reconcilable with prevailing theories of thought, be it Freud's theory of mind as manipulating biological energies; the behaviorists' standpoint that thought is simply silent speech; or the Gestalt psychologists' emphasis on context dependency, interconnectedness, and emergent quality of thought. In essence, the vision of cognition as symbol manipulation revived the Enlightenment view of thought as a combinatorial calculus. For Condillac, d'Alembert, Condorcet, and other Enlightenment philosophers, the healthy mind worked by constantly breaking down ideas and sensations into their minimal elements, then comparing and rearranging these elements into novel combinations and permutations.

The view of thought as symbol manipulation also revived the old dream of a logic of scientific discovery, the existence of which Karl Popper had so vehemently disclaimed. Computer programs such as Bacon managed to infer scientific laws from data, and artistic creativity was modeled on the same combinatorial principles. Computer programs were written that composed music, wrote stories, and designed new Palladian villas and prairie homes. Leibniz's dream of a universal characteristic that would assign a number to each concept and reduce each problem to calculation seemed to have come true. Alongside Babbage and Pascal, Leibniz had designed one of the first computers.

Through the medium of the computer, Enlightenment psychology reentered modern psychology. This is, however, only half the story. Just as George Boole had set out in the mid-nineteenth century to derive the laws of logic and probability from the psychological laws of human thought, researchers such as Simon and Newell tried to enter the results of psychological research about human thought into their computer programs. For instance, the concept of heuristics that speeds up search in a problem space proved to be essential for intelligent programs. Heuristics are smart rules of thumb that humans apply in a world of unknown risks where optimization, such as Bayesian probability updating and maximizing expected utility, is impossible or would cost too much time (*see* Decision Making: Nonrational Theories).

The metaphor of the mind as computer must be distinguished from John von Neumann's (1903–57) metaphor of the

brain as computer. Von Neumann, known as the father of the modern computer, looked at similarities between the nervous system and computer, neuron and vacuum tube – but added cautionary notes on their differences. Turing, in contrast, believed that the observation that both the modern digital computer and the human nervous system are electrical was based on a superficial similarity. He pointed out that the first digital computer, Babbage's Analytical Engine, was mechanical rather than electrical and that the important similarities between computer and mind concern function rather than hardware.

How quickly did the metaphor of the mind as computer gain acceptance among cognitive psychologists? Consistent with the tools-to-theories heuristic – which says that new scientific tools suggest new metaphors of mind, society, or nature but are accepted by a scientific community only after its members have become users of the tool – the mind as computer metaphor was not broadly accepted until the 1970s and 1980s. Before the advent of personal computers, researchers had little direct contact with the large mainframe computers, and for those who did, computers were a source of constant frustration. For instance, in an average week in 1965–66, the PDP-4C computer of the Center for Cognitive Studies at Harvard saw 83 h of use, but 56 h of these were spent on debugging and maintenance. A 1966 technical report of the Center was entitled "Programmanship, or how to be one-up on a computer without actually ripping out its wires." The metaphor of the mind as computer became widely accepted only after the tool had become part of the daily routine in psychological laboratories – after the advent of personal computers.

From Thought Experiments to Simulation

Thought experiments in fields from physics to political science are research tools used in situations where no data can be obtained, such as counterfactual historical scenarios. The computer created a new species of thought experiments: computer simulation. Jay Forrester's Club of Rome world resource model – which predicted worldwide famine followed by war in the first third of the twenty-first century – is one of the best-known early social science simulations. Robert Axelrod's classic 'prisoner's dilemma' computer tournament demonstrated the success of a simple social heuristic called tit-for-tat and became the model for numerous simulations in game theory, reciprocal altruism, and political science. Simulations force researchers to specify their theoretical ideas precisely and have become a tool for discovering new implications of these ideas. In some fields, precise articulation of assumptions has become a requirement for what constitutes a theory: what cannot be simulated does not deserve to be called a theory.

Computer simulation allows for the modeling of dynamic systems, such as the evolution of social structures through repeated interaction between individuals. It is a truly new form of experiment, but social scientists are divided over its role in research. In artificial intelligence, organizational theory, and demography, for instance, simulation has a long tradition. In sociology, in contrast, simulation is still rare and frequently disparaged. Simulation tends to play a minor role in fields with a deeply entrenched distinction (or even hostility) between theoretical and empirical research, such as sociology, and where computers are heavily used for the analysis of empirical data. Perceived as the instrument of the 'other,' number-crunching camp, the computer's theoretical possibilities tend to be forgotten.

A World of Numbers and Statistics

When the statistician Karl Pearson assembled the famous *Biometrika* statistical tables between 1914 and 1934, he used a 50-lb Brunsviga calculator and numerous clerks. The 1946 ENIAC – commonly referred to as the first modern digital electronic computer using vacuum tubes – could calculate 5000 additions per second, that is, did the work of a whole factory of clerks. Fifty years later, a tiny and relatively inexpensive Pentium chip could conduct over 500 million operations per second. This explosion of calculating power together with decreasing cost and size has had a dramatic impact on the social sciences, both positively and negatively. In some fields, the emphasis has shifted from collecting qualitative observations to quantitative data, and from *a priori* theoretical thinking to the *post hoc* interpretation of significant correlations.

At the end of World War II, half of the articles in the *American Sociological Review* and *American Journal of Sociology* lacked any kind of quantitative mathematical analysis; 30 years later, this number had decreased to about 13%. In psychology, as in sociology, the predominant quantitative methods before the advent of electronic computers were descriptive statistics, such as means, variances, percentages, correlations, and cross tabulations. With the introduction of fast calculators, the social sciences have witnessed a rapid growth in the usage of computationally expensive statistical methods, including factor analysis, cluster analysis, analysis of variance, and multiple regression. The computer also provided tools that could make data structures visually transparent and help researchers see underlying structures – called exploratory data analysis. Sociologists, demographers, and anthropologists were finally able to analyze census data, voting polls, and other large samples in a short time.

Computerized statistical packages such as SPSS (Statistical Package for the Social Sciences) have not only helped but also hindered progress. Their ease of application (e.g., compute 'everything by all') has often replaced statistical thinking with statistical rituals. One widespread ritual is null hypothesis testing, in which the researcher mechanically tests whether data significantly deviate from a null hypothesis ('chance'), without ever specifying the predictions of the research hypothesis and of competing hypotheses, and without measuring effects and constructing substantive theories of some depth. As a consequence, researchers tend to skim through computer printouts looking not at the data but at the significance level of the correlations or chi-squares and engage in *post hoc* explanations for whatever comes out significant. The consequence of this grave misuse of computational power is an increasing number of false positive results and flawed research featuring significant effects that cannot be replicated.

While fast computers made routine statistical analysis feasible, they also became enlisted in the 'big data' program

that aims at dispensing with statistical sampling theory, and theory in general. Using huge amounts of data provided by Google and other sources, claims were made that sampling theory would be obsolete because '$N = \text{All}$,' that causes could be substituted by correlations, and that with enough data, the numbers would speak for themselves. For Simon, the computer promised a theory of mind, for proponents of big data, it meant the end of theory.

Research and Teaching Assistance

Next to data analysis, the most common function of computers in the social sciences is that of an efficient and patient research assistant. A computer can serve as a librarian who searches for relevant publications and historical records; as a data bank manager who stores and retrieves narrative information, qualitative and numerical data; as a secretary who edits and files texts, footnotes, and references; and as a fast electronic mail system that facilitates contacts with colleagues worldwide. In experimental psychology, computers run entire experiments with humans and animals; they present the experimental stimuli and record the participants' responses.

This interactive use of computers would not have been possible without the invention of the personal computer that replaced the large mainframes. Engelbart's invention of the mouse exemplifies how human abilities such as hand–eye coordination can be exploited to design appropriate tools with which humans can almost intuitively interact with computers. In social science teaching, human–computer interaction can increase the participation of all students, whereas in the traditional classroom small groups of students often tend to dominate the discussion. Facebook, chat rooms, and the World Wide Web in general have become new and cheap sources of 'big data' for analyzing social networks and consumer behavior. The Web in turn has generated legal and ethical problems concerning secrecy and data protection, motivating revisions of copyright, tax, and criminal law.

The Computer Revolution

Has the computer fundamentally changed the social sciences? As we have seen, its impact differs across the social sciences. The invention of the modern computer has increased interdisciplinarity through the creation of *cognitive science*, consisting of artificial intelligence, psychology, philosophy, linguistics, anthropology, and neuroscience. However, sociology is notably absent from that list. Electronic mail and the Internet have made international collaboration easier and faster than ever. Simulation, expert systems, neural networks, and genetic algorithms would be unthinkable without high-speed computers, as would statistical analyses of large bodies of data. In these respects, the social sciences today have a repertoire of powerful new tools and opportunities.

Has the computer revolutionized our conception of mind and society? The answer seems to be yes if we use the original meaning of the term – a re-volution, that is, a return to earlier conceptions. The metaphor of the mind as computer, for instance, has resurrected the combinatorial view of cognition of the Enlightenment and Adam Smith's ideal of a division of labor. Thinking, problem solving, creativity, and scientific discovery came to be explained by a hierarchically organized mind that decomposes complex problems into simpler subroutines. In this way, theories of mind and society that had existed before computers were expanded and perfected.

Abstract

Auguste Comte is the founder of the philosophy of positivism, the disciplines of sociology and the history of science, and the Religion of Humanity. These innovations were inspired by his desire to reorganize society after the upheaval of the French Revolution of 1789. Influenced by his education at the Ecole Polytechnique and his 7-year association with the social reformer Henri de Saint-Simon and disillusioned by the revolutions, monarchical regimes, republics, and empires that punctuated his existence, Comte rejected purely political and institutional reforms as ineffective. In the *Cours de philosophie positive* (1830–42) and the *Système de politique positive* (1851–54), he argued that social harmony could occur only if individuals were brought together by a consensus that was both intellectual and emotional in nature. Ideas as well as feelings had to be reordered. He first created positivism and its keystone, sociology, and then devised the secular 'Religion of Humanity' in order to construct a new cohesive society that would encompass the conservatives' call for order and the leftists' insistence on progress. Comte's doctrine had a large impact in Europe, the USA, and Latin America. It also influenced sociology, the history and philosophy of science, historiography, and anthropology.

Auguste Comte is the founder of the philosophy of positivism, the disciplines of sociology and the history of science, and the Religion of Humanity. These innovations were inspired by his desire to reorganize society during the period of upheaval following the French Revolution of 1789. Living through several revolutions, monarchical regimes, republics, and empires, Comte rejected purely political and institutional reforms as ineffective. Instead, he argued that social harmony could only occur if individuals were brought together by a consensus that was both intellectual and emotional in nature. Ideas as well as feelings had to be reordered. Comte's search for a consensus derived not only from the anarchy of the postrevolutionary period but from the instability in his own life, which led him to view inner harmony as a sign of health. He created positivism and its keystone, sociology, to construct a new cohesive society that would encompass the conservatives' call for order and the leftists' insistence on progress. This article will investigate Comte's personal and intellectual development as well as his contributions to knowledge and politics.

Life and Main Works

The son of a minor bureaucrat, Comte was born on 19 January 1798 in Montpellier, France. Growing up in this center of counterrevolutionary activity, he was deeply affected by the chaos stemming from the French Revolution. By age 14, he renounced both the monarchy and God, alienating his royalist, Catholic parents. Comte's rebelliousness was shared by many members of his generation, who longed for a sense of community and new principles of legitimacy that would stabilize moral and political life. His insubordinate behavior led to his expulsion from the Ecole Polytechnique, the prestigious Parisian engineering school, which had admitted him in 1814 because he had performed brilliantly on the entrance examination. (He was especially gifted in mathematics.) After his dismissal from the Ecole Polytechnique, in 1816, he committed himself to fulfilling the radical revolutionaries' dream of erecting a secular republic.

Living in Paris, he accepted in 1817 the position of secretary to Henri de Saint-Simon, who is often considered an early socialist. They became close collaborators in many journalistic enterprises. However, in 1824 they parted ways after Comte accused him of trying to take credit for his 'fundamental opuscule', the *Plan des travaux scientifiques nécessaires pour réorganiser la société*, which outlined his social ideas. Although Comte later denied Saint-Simon's influence, the older reformer showed him that they were in an era of transition that had to be completed by constructing a new society founded on industry and a new system of scientific knowledge, the 'positive philosophy'. This philosophy centered on the scientific study of society. Using his talent for synthesis and system building, Comte brought to fruition the seminal ideas strewn haphazardly throughout Saint-Simon's frequently incoherent works.

In 1826 Comte launched a course in positive philosophy in his apartment. Reflecting the high regard in which he was held, the course was attended by the famous economist Charles Dunoyer and many leading scientists, including Henri de Blainville, François Arago, Joseph Fourier, Alexander von Humboldt, and François Broussais. Yet after several lectures, Comte suffered a mental breakdown and spent 8 months in an asylum run by J.-E.D. Esquirol. He struggled against manic depression and paranoia for the rest of his life.

Moreover, he found it difficult to secure a career worthy of him, though he tried repeatedly to obtain a chair in analysis and mechanics at the Ecole Polytechnique and gain admission to the Collège de France. However, scientists and other scholars refused to consider him seriously because rumors about his mental instability continued to circulate, his prickly character made it hard for him to network, he never published a monograph on a particular science, and he never received an advanced degree. After working as a mathematics tutor and journalist, he obtained a lowly teaching and administrative position at the Ecole Polytechnique, where he remained from 1832 to 1851.

Between 1830 and 1842, Comte wrote his most important work, the *Cours de philosophie positive*. It covered the history of the sciences, demonstrating that it was time for the study of society to become a science as well. Once 'sociology' was

established, the system of scientific knowledge would be completed. Comte called this system 'positivism'. The *Cours* attracted the attention of several famous scholars and writers, including John Stuart Mill and Emile Littré, but they eventually became estranged from him.

Another person who experienced a rupture with Comte was his wife, Caroline Massin. A penniless director of a reading room, she married him in 1824 and helped him recover from his attack of madness. They had a tumultuous marriage, marked by his fits of jealousy, and they separated in 1842. To punish her, he later called her a prostitute.

Three years after their separation, Comte fell in love with Clotilde de Vaux, who was 17 years younger than him. Having been abandoned by her husband, this aspiring writer grew close to Comte but resisted his sexual advances. After she died of tuberculosis in 1846, Comte made her into his muse.

After her death, Comte became more of an activist, thanks in part to the reforming impulses let loose by the Revolution of 1848. He established his own club, the 'Positivist Society', to launch the positivist movement, and he wrote a manifesto, the *Discours sur l'ensemble du Positivisme*, which was a more extensive introduction to his philosophy than his *Discours sur l'esprit Positif* of 1844. Disappointed that scientists and other intellectuals neglected him, he targeted two new groups, workers and women, whose social roles were highlighted in the *Système de politique positive*. Published in four volumes between 1851 and 1854, this work expressed his political and social ideas. It promoted the importance of the emotions, established the Religion of Humanity, and made morality the seventh science. Many scholars blame his relationship with de Vaux for Comte's alleged decline into religious, sentimental thinking. Yet there was no sudden break in his career, for from the start he distrusted the purely scientific spirit, committed himself to moral reform, and sought to create a new belief system to replace traditional religion.

The last years of Comte's life were marked by increasing seclusion and conservatism. Much to the displeasure of many of his disciples, Comte supported the coup d'état of Louis Napoleon in 1851, partly out of fear of anarchy and partly out of hope of converting him to positivism. He also redoubled his efforts to gain the support of women, especially because he was disappointed that workers remained committed to socialism and would not consider his political system. To gain women's attention, he wrote the *Catéchisme positiviste* (1852), which featured a series of dialogues between a positivist priest of Humanity and a woman. Although not a feminist, he proclaimed that women would be given new respect in the positivist era because they would be essential moral agents, encouraging the development of sociability and ensuring a compassionate society. Later he published *Appel aux conservateurs* (1855) to persuade conservatives to join the positivist movement. Finally, in 1856 Comte wrote the *Synthèse subjective*, which explored the importance of images and the emotions in the context of mathematics and logic in order to bring together the three facets of our existence: intellectual speculation, affection, and activity. Dependent financially on a small group of followers, he died of stomach cancer in Paris on 5 September 1857.

Auguste Comte was a brilliant visionary. He sought to create in society the harmony and stability that he could not find in his private life or in postrevolutionary France. However, his paranoia, egoism, and dogmatism impaired his personal relations and his ability to launch a viable political and intellectual movement. He never gained the fame or power that he had hoped to achieve. Yet after his death, his ideas had a large influence on intellectual and political life both in Europe and on other continents.

Positivism and the History of Science

Comte's original version of positivism, which is far from the scientism with which it is often associated, had both a theoretical component and a practical, or political, aspect. It did not celebrate the sciences for their own sakes or seek to be value free as scientific systems often claim to be. Positivism sought to facilitate useful, constructive activity that would improve the human condition. In particular, it promoted the establishment of a new secular, republican society imbued not only with the certainty that came with scientific knowledge but with 'altruism', a word he coined around 1850 in order to counteract the sense of disconnectedness pervading modern society. Above all, Comte wanted members of society to be united by an intellectual consensus on fundamental aspects of knowledge and by emotional bonds in order to improve themselves and their natural and social environments.

Being an idealist, Comte believed that intellectual confusion was at the root of the postrevolutionary anarchy because ideas always determined the social structure. Rejecting the conventional abstractions and practices of traditional religion and politics as useless, he sought to create an intellectual revolution that would first lead to a moral revolution and then to a political and social revolution. An intellectual revolution would occur if one placed knowledge of society on a sure foundation to attain more control over it. To this end, he recommended extending the scientific, or 'positive', method from the investigation of nature to the study of politics and society.

The 'positive' designated the certain, precise, useful, relative (as opposed to the absolute), and constructive (as opposed to the negative). Positive laws must avoid references to God and to other first and final causes or substances, which were incomprehensible. These laws had to express the spatial and temporal relationships between phenomena and do so in such a way as to enable scientists to make predictions affecting the world of action. To arrive at these laws, scientists should try to replicate as much as possible the deductive, rational approach of mathematics and eschew pure empiricism because collecting isolated facts was a waste of time. To help them to construct abstract laws and theories, Comte sought to free scientists from the tedious task of direct observation. He insisted that individuals could not even make observations and retain facts without first formulating a theory to guide their perceptions. He also promoted provisional hypotheses as important ways of advancing scientific understanding when concrete, observed facts were missing. Furthermore, scientists should use their imagination to create 'scientific fictions', or hypothetical cases, to fill in poorly understood areas. Comte recognized the role of aesthetics and the subjective in formulating scientific hypotheses. To avoid giving reason excessive importance in scientific research, he refused to offer universal logical rules of scientific

procedure and scientific proof. Indeed, he insisted that one could never arrive at absolute truth, that is, an exact understanding of reality; everything was relative in his mind. Comte's only injunction was that every positive theory had to refer on some level to real, concrete phenomena that could be observed directly or indirectly.

Reflecting the impact of nineteenth-century historicism, Comte asserted, moreover, that one could not truly understand a phenomenon without grasping its history. To comprehend the positive method, one had to see its development in the major sciences, each of which had to be considered in relation to its own history, the history of the other sciences, and the history of society in general. The *Cours de philosophie positive* highlighted the history of science, which Comte believed was the most neglected and important part of the development of humanity.

The *Cours* revolved around Comte's renowned 'law of three stages'. This law demonstrated that as the mind went from one mode of thinking to another, it generated a different theoretical system, which in turn shaped the political and social system. There were three stages of development. In the theological stage, people used supernatural ideas, such as one or more gods, to link their observations. There were three phases of this stage: fetishism, which located gods in phenomena; polytheism, which promoted many gods; and monotheism, which held up one god. In a theological society, priests and military men ruled. The theory of divine right was the reigning political doctrine, while conquest was the principal material activity. In the transitional, metaphysical stage, God was replaced by a personified essence or abstraction, such as Nature or Reason. Lawyers and metaphysicians dominated society. The doctrines of popular sovereignty and natural rights were important in politics. More material activities were geared toward production. Finally, in the positive stage, supernatural and abstract forces would be replaced by scientific laws describing how, not why, phenomena functioned. Industrialists and positive philosophers would run a republic. Production would replace conquest as the goal of society.

The *Cours* also introduced Comte's famous 'classification of the sciences'. Each science went through the theological and metaphysical stages and finally became positive according to the simplicity of its phenomena and the distance of these phenomena from humans. Mathematics, which was not a 'direct' natural science, demonstrated the characteristics of the positive method. The positive method was then established in astronomy, physics, chemistry, and biology in that order. Each science depended on the simpler sciences that came before it in the hierarchy of sciences and could not advance to the positive stage until the preceding ones did. Comte argued against reducing one science to another, for each had its own distinctive subject matter and methodology. Moreover, Comte warned against the widespread use of mathematics in scientific investigation, especially in biology and sociology. He particularly disliked the use of statistics in sociology because it neglected the complexities of human nature.

The point of Comte's laws of three stages and classification of the sciences was to demonstrate the inevitable triumph of the positive method in every area of study because all aspects of knowledge were interrelated and the mind sought homogeneity. Now that mathematics, astronomy, physics, chemistry, and biology were positive, it was time for the positive method to be extended to the study of politics and society, which involved the most complex phenomena and the ones closest to humans. The study of politics and society was the last stronghold of theology and metaphysics. Its takeover by science would mark the beginning of a new era in history: the positive era.

In the *Système de politique positive*, written in the 1850s, Comte added a seventh science, morality, which covered the individual. It reflects his growing awareness of the complexity of the human condition and of human nature, especially the role of the emotions in shaping our ideas and actions. He wished to give sociologists more guidance when they had to tackle matters relating to the relationship between society and the individual.

He was also eager to respond to critics, who accused him of endorsing an authoritarian intellectual and political program. Comte admittedly did not see any criticism of his works thanks to his adoption in 1838 of a regime of 'cerebral hygiene', which forbade him from reading contemporary books, journals, and newspapers (except scientific bulletins). He would not brook any kind of debate on his ideas and insisted that dogmatism was the normal state of the human mind. Yet aware of the negative response to his own dogmatic pronouncements and to his support of Napoleon III, he recognized that he had a reputation as an authoritarian thinker. To counter the notion that he neglected the importance of the individual, he created this new science of morality and repeatedly insisted that he respected individuals, who in his mind, were interdependent parts of an organic whole, society. It was the excessive individualism of his period that he claimed was the object of his ire.

Sociology

Comte named his science of society 'sociology' in 1839, giving it a distinctiveness and importance in his system that it never had in Saint-Simon's work. Once it was created, positivism, the system that encompassed all scientific knowledge, would be unified and complete because all our concepts would be scientific and thus homogeneous. In addition, sociology would help unite knowledge by making all the sciences focus on improving humanity and its conditions of existence.

Comte's sociology had two parts, social statics and social dynamics. They stressed the interconnectedness of the members of the human species in space and time. Both had a moral mission, that of countering the egoism and selfishness of the modern age.

Social statics was devoted to studying the social order. It investigated the elements that kept society together. One crucial element was the family, which taught the importance of love as the key to moral self-improvement. This love was transferred to one's family and eventually to all of humanity. In short, social statics cultivated an individual's feelings of solidarity with other members of society. Although Comte's atheism was unusual in the early nineteenth century, his view of the sanctity of the family and his stance on other moral issues were conventional. He wanted to distance himself from contemporary reformers, such as the Saint-Simonians and Fourierists,

whose questioning of traditional social institutions, such as marriage, hurt their movement.

While social statics cultivated people's sense of solidarity with their contemporaries, social dynamics provided them with a feeling of connection with past and future generations of the human species. Social dynamics focused on social development, which Comte considered continuous, necessary, orderly, and limited. Each social state grew out of the preceding one and produced the next social configuration. Reflecting Comte's approval of different aspects of Lamarckism, the crucial feature of this development was that through exercise, the unique characteristics of the human species – intelligence and sociability – became more dominant within both the individual and society. The growth of reason and altruism ensured progress. Reflecting this progress, the law of three stages was the main principle of social dynamics.

In addition to sketching the two divisions of sociology, Comte delineated the new science's methods: observation, experimentation, and comparison. Because every aspect of society had many connections, Comte argued that observations should be varied. Sociologists should observe ordinary events, common customs, languages, different types of monuments, and other mundane social phenomena. Comte's grasp of the significance of everyday life has been buttressed by recent trends in social and cultural history. As for experimentation, Comte maintained that its use posed problems in sociology because of the impossibility of isolating any of the circumstances or consequences of a phenomenon's actions. He explained that a sociologist, like a biologist, should study pathological cases, which were forms of indirect experimentation. Because the pathological was simply a variation of the ordinary, examining periods of chaos, such as a revolution, provided clues to what was normal. In short, by studying social disorder, sociologists would gain insights into the laws of social harmony and history. As for comparison, Comte believed in the importance of comparing human and animal societies, different existing states of human society (i.e., savage and civilized peoples), and different consecutive social states.

The law of three stages of social dynamics and the comparative method of social statics point to the importance of history in Comte's system. He did not include history as one of the fundamental sciences, but he did think that the historical method was sociology's chief means of scientific investigation. History helped provide people with a sense of social solidarity and continuity, in short a feeling for humanity in the world and an understanding of their own role in its evolution.

Sociology was not simply a science; it had a practical, political mission, that of solving social problems. Because everyone would agree on the most significant intellectual and moral principles, the establishment of sociology would lead to the intellectual consensus required to build a stable industrial society. Like other scientific laws, sociological laws would facilitate predictions about social phenomena in the future. Armed with this knowledge, sociologists could construct policies to deal with social problems. In short, sociology would provide the rational principles necessary to reform society.

Seeking to go beyond the bitter partisan politics that marked the postrevolutionary era, Comte offered sociology as a way to create a society that would appeal to both the right and left. It would please the former by stressing order and appeal to the latter by promoting progress. Sociology could unite order and progress because social life, when dominated by universal love, would have order as its basis and progress as its objective.

Positive Politics and the Religion of Humanity

As mentioned above, Comte believed that the unique characteristics of the human species, that is, intelligence and sociability, developed through exercise within both the individual and society. This theory reflects Comte's multidimensional view of human nature, which was reinforced by romanticism. To him, the emotions were closely connected with the intellect, which they simulated. Because social needs were both intellectual and emotional, social reorganization had to involve the heart as much as the mind. In the first phase of his development, Comte emphasized the importance of creating a system of ideas that could be shared by all people. In this positivist system, sociology led everyone to focus their thoughts on the needs of society, or humanity. In his second phase, Comte stressed the necessity of reinforcing the intellectual consensus by encouraging emotional ties among individuals through the Religion of Humanity. Everyone should not simply think about Humanity but love it as well. In short, an increase in intellectual well roundedness would lead to a growth of altruism. Finally, moved by their love for Humanity, individuals would act to improve themselves, their society, and their material or natural environment.

Comte's promotion of universal love was inspired by his horror of the abuses of modern industrial and capitalist society. He believed that the division of labor, which was necessary for progress, increased specialization and made people egotistic, narrow-minded, and selfish. The lower classes suffered the most from the indifference of the rest of society. Their conditions of existence were deplorable. Existing political parties, tied to the old theological and metaphysical principles, could not solve social problems.

Comte created a secular religious culture to bring all individuals together, including the workers, whom he found superior to their employers. He took much criticism for reviving religion after he had called for the end of theology. However, considering its Latin root, '*religare*', Comte pointed out that religion did not have to relate to one or more deities but could be reduced to its essential function of regulating and bringing together with a view to improving society in some way. To him, religion regulated both private life and social existence, which were connected. Inner harmony was linked to social harmony, and both led to health and happiness.

Religion united the mind, heart, and activity, the three aspects of human existence. Stimulated by religion, the mind and heart could work together to vanquish the rampant egoism of society. Both shaped activity, for sentiments and opinions determined and influenced what we did, respectively. Given that the positivist regime cultivated altruism, activity would be directed toward social ends, and individuals would increase their cooperation to achieve those goals. Religion entailed this social cooperation as well as the cooperation between the mind and heart. Because intellectual and emotional capacities were developing and working together and individuals were increasingly cooperating, Comte announced his new 'law' that

human nature and society were becoming more and more religious. People were becoming more sympathetic emotionally, more synthetic intellectually, and more synergetic in terms of activity. The traditional battle between the intellect and the emotions was over.

Enthusiastic about his new Religion of Humanity, which had traces of the Catholicism of his youth, Comte designed new sacraments, temples of Humanity, a list of essential books ('The Positivist Library'), and a calendar of secular saints. Included in the Positivist Calendar were such luminaries as Aristotle, Caesar, Dante, Shakespeare, Joan of Arc, and Heloise. The cult of Humanity, including a cult of 'Woman', would honor individuals who had contributed to civilization with a continuous series of festivals. Comte deliberately constructed a collective memory. However, he also wanted to ensure that individuals who had not achieved public fame lived on in the memory of their families or others whom they had touched in their lives. In this way, they would gain immoratlity, despite the fact that the notion of heaven would disappear.

Comte also recognized that political action in the new age would consist of using education and the arts to shape collective sentiments, beliefs, and representations. Outlining the entire curriculum, he insisted that public schools offer boys and girls of all classes a broad education that cultivated feelings of sociability besides an understanding of the seven sciences. Having lived under Napoleon I and Napoleon III, both of whom used iconography to further their agendas. Comte also grasped the importance of visual culture in promulgating political and social messages. To that end, he had his portrait and bust done by Antoine Etex to immortalize his own image, he devised positivist flags with a young mother representing Humanity, he designed Temples of Humanity, and he made up simple charts of the human mind. In addition, he wanted the color of the positivist movement to be green, in contrast to the white of the royalists and the red of the radical revolutionaries. People might be brought together by common beliefs, but emotional bonds, developed with the aid of visual identifiers, were also important. Every means possible was to be harnessed to create a religious culture that could maintain social cohesion.

The Religion of Humanity also assumed features of fetishism, the most emotionally intense and concrete form of religion. Comte was one of the first thinkers to celebrate primitive religion and see its benefits. Unlike modern men, fetish worshipers, according to Comte, admired what was concrete and showed much regard for the natural world. Comte called the Earth, the 'Great Fetish'. Like the 'Great Being', that is, Humanity, the 'Great Fetish' ruled our lives and demanded respect. Indeed, Comte's attitude toward the Earth helps to explain why he chose green as the color of his movement. Positivism, the most advanced stage of history, would lead full circle to the beginning of civilization, reflecting his increasing doubts about the benefits of science and progress.

In his *Synthèse subjective*, he pointed out the dangers of studying mathematics, the science that he had taught since he was a young man. He argued that in order to counter its aridity, it should be injected with sentiments by adding graphic and phonic elements. Poetry, in particular, should be connected to the sciences. By the end of his life, he was hopeful that positive philosophers, generalists with knowledge of all the sciences, would become poets, creating verses that celebrated Humanity.

In short, although Comte's doctrine was scientific in nature, he insisted on the limits and dangers of the sciences in promoting specialization and narrowness, and he recognized the importance of practical activity to which most people were drawn. To prevent the emergence of a dictatorship of scientists, Comte recommended that there be two separate powers that would hold each other in check. The temporal power would be composed of industrialists, who would control the practical, material activities of society. The spiritual power would consist of positive philosophers, who would govern the world of ideas, opinions, and feelings. The philosophers' chief assistants would be workers, who would be finally incorporated into society, and women, who would make nurturing the goal of public life and would shape public opinion through salons. Women and workers represented the oppressed elements of society that were preserved from the shallow, materialist culture of the day. Both needed to be treated with respect for the advent of positivism to occur.

Comte was eager to address the oppressed not only to attract more adherents to the positivist movement, but to stress the importance of our common humanity. He took elements of the socialist and feminist agendas to appeal to the working class and women and hoped his privileging of fetishism would help bring him the support of 'primitive' races, including blacks. He frequently attacked slavery. Although positivism was often used later during the Third Republic to justify the French 'civilizing mission', Comte also condemned nationalism and imperialism, including France's takeover of Algeria. Anything that divided humanity instead of bringing it together incurred his disapproval. To display positivism's esteem for other faiths, he frequently commended Mohammed and Islam.

To create a more pacifist, more tolerant world, Comte argued in favor of breaking up large states into small republics, which were akin to city-states. Ideally, there would be 500 of these small republics throughout the globe. Because they would be about the same size, with 1–3 million people, and they would share the belief system of the Religion of Humanity, there would be less chance of war. The capital of this positivist world would be Constantinople, the city that Comte believed could best bring together the East and West.

Assessment and Influence

Comte's system was a grand synthesis designed to appeal to diverse philosophical and political positions. It incorporated ideas from many European thinkers, including Bacon, Descartes, Hume, Montesquieu, Condorcet, the Ideologues, the Scottish Enlightenment philosophers, Maistre, Gall, Kant, and Herder. In terms of politics, Comte supported the moral concerns associated with the counterrevolutionaries and remained committed to the leftist tradition that political authority must aid the people. In searching for a synthesis that was both objective and subjective in nature, Comte pursued the middle way between extremes in all realms. He sought to balance the needs of the heart and those of the mind, rationalism and empiricism, induction and deduction, materialism and idealism, religion and science, feminism and patriarchalism, democracy and authoritarianism, and individuality and sociability.

Yet on balance, Comte's philosophy tends to be authoritarian, dogmatic, and grandiose. He seemed eager to create a conformist, homogeneous society. Many of his so-called scientific assertions, including the law of three stages, are replete with assumptions. Paradoxically, several of the strengths of his system, that is, the diffuseness of his endeavor and his tendency to see the complexity of each problem, turned out to be weaknesses because they caused him to lose support in his own day. The left found him illiberal and religious, while the right considered him blasphemous and anarchical.

Nevertheless, Comte's thought was extremely influential. Because it was vast and complex, people took from it what they wanted. During his lifetime, it attracted numerous followers in France, the United Kingdom, the United States, and Latin America. His two most famous disciples, John Stuart Mill and Emile Littré, made positivism into a manifesto for the scientific age. George Henry Lewes popularized the positivist doctrine as did Harriet Martineau, who wrote an abridged translation of the *Cours* (1853), which Comte praised as superior to his original work.

Individuals on the left and right employed elements of positivism to bolster their diverse political causes. Left-leaning politicians of the Third Republic used positivism in their campaign against the Church. Enthusiasts included political leaders Jules Ferry and Léon Gambetta, and the writer Emile Zola. On the other side of the political spectrum, Charles Maurras employed positivist principles to enhance the proto-fascist doctrine of the *Action Française*. In Latin America, positivism proved very attractive to republicans, especially in Brazil, whose flag displays Comte's motto "Order and Progress". But Positivism was often used to bolster dictatorial regimes, such as that of Porfirio Diáz in Mexico. In the United States, reformers, such as David Croly, Thaddeus Wakeman, Edward Bellamy, Herbert Croly, and Lester Ward, embraced positivism as an alternative to religion and appreciated his emphasis on an intellectual elite who could push for social change.

Comte also influenced the humanities and social sciences. Philosophers of science have been interested in his approach to hypotheses and his explanation for the uniqueness of science. His work may have influenced Claude Bernard, Marcelin Berthelot, Paul Janet, Ernst Mach, Wilhelm Ostwald, and Pierre Duhem. Logical positivists, such as A.J. Ayer, Otto Neurath, Rudolf Carnap, Moritz Schlick, and Hans Reichenbach, shared Comte's concern with problems of verification and grappled with his thought. Positivism long dominated European historiography; Thomas Buckle is the usual example of a positivist historian. Lucien Lévy-Bruhl introduced many of Comte's ideas into anthropology. Through Emile Durkheim, positivism influenced sociology, which adopted Comte's concern with social solidarity and harmony. Other social scientists affected by Comte include Alfred Espinas, Herbert Spencer, Hippolyte Taine, Ernest Renan, Charles Booth, and Patrick Geddes. Comte's thought remains relevant today, when people still grapple with many problems that he highlighted, such as the role of affectivity in education and the sciences, the roots of moral crises, and the significance of collective memory. Particularly at a time when global interests are paramount, Comte's call for a commitment to humanity as a whole and the environment bears renewed examination.

Concentrated Disadvantage

Paul A Jargowsky and Natasha O Tursi, Center for Urban Research and Education, Rutgers University – Camden, Camden, NJ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Concentration of disadvantage' refers to the phenomenon of spatial clustering of economically or socially disadvantaged individuals within a set of neighborhoods and the resulting feedback effects that exacerbate the problems of poverty. The central concept is the disproportionate share of disadvantaged persons in geographic neighborhoods lacking critical resources, such as access to quality healthcare and quality education. Areas of concentrated disadvantage around the world are referred to by different terms such as ghettos, barrios, slums, favelas, and banlieues, each with a different set of connotations. Concentration and its effects are a critical component in the study of poverty and disadvantage.

Introduction

'Concentration of disadvantage' refers to the phenomenon of spatial clustering of economically or socially disadvantaged individuals within a set of neighborhoods and the resulting feedback effects that exacerbate the problems of poverty. The central concept is a disproportionate share of disadvantaged persons in geographic neighborhoods lacking critical resources, such as access to quality healthcare and quality education. Such neighborhoods typically have high crime rates, in part due to a flourishing underground economy (Anderson, 1990).

To characterize areas of concentrated disadvantage, social scientists use variables that are indicators of elevated levels of neighborhood socioeconomic distress. Depending on the availability of data, these variables include the poverty rate, median income, joblessness, housing quality, and family structure. These data points are individual-level characteristics that when aggregated to the neighborhood level indicate concentrated disadvantage. In the United States, which has an officially sanctioned poverty line, concentration of disadvantage is sometimes measured by examining the spatial concentration of poor persons. Jargowsky (Jargowsky, 1997) defines the 'concentration of poverty' as the proportion of an area's poor persons residing in census tracts where the official poverty rate is 40% or more. On average, in these high-poverty neighborhoods, fewer than half of adult males are in the labor force and more than half of children live in single-parent families (Jargowsky, 2013).

Exploiting the correlation of poverty with other indicators of socioeconomic disadvantage, the Project on Human Development in Chicago Neighborhoods created a multidimensional measure of concentrated disadvantage based on census tract levels of welfare receipt, poverty, unemployment, female-headed households, percentage black, and density of children (Sampson, 2012: 100). Neighborhoods with higher disadvantage are marked by lower collective efficacy and greater exposure of neighborhood residents to criminal victimization. Neighborhoods of concentrated disadvantage are highly durable over time, rarely experiencing fundamental socioeconomic progress (Sampson, 2012), outside of a few well-publicized cases of gentrification. Moreover, residence in high-poverty neighborhoods is highly persistent and is transmitted intergenerationally, especially for African-Americans (Sharkey, 2008).

Concentration of poverty and disadvantage must be distinguished from poverty and disadvantage per se. A given city or metropolitan area can have a greater or lesser amount of socioeconomically disadvantaged persons. Yet if those persons are spread evenly across the landscape, there would be no concentration. An extremely poor city, therefore, could have no concentration of poverty, while a relatively affluent city in which a small number of poor persons live alone in a specific set of neighborhoods could have total concentration of poverty (Jargowsky, 1997: 17). In practice, however, the level of poverty and the concentration of poverty are frequently correlated.

Concentration of disadvantage must also be distinguished from the concept of the 'underclass' or 'underclass neighborhoods' (Ricketts and Sawhill, 1988). While no one definition of the underclass ever achieved general acceptance, the term generally refers to people who are not just poor, but fundamentally unable to access the class structure due to structural unemployment, hostility to mainstream values, criminal tendencies, or addictions that render them incapable of holding on to a job (Myrdal, 1963; Glasgow, 1980; Auletta, 1982). Such neighborhoods can develop a 'social milieu' that fosters low labor force attachment, out-of-wedlock childbearing, drug and alcohol use, and other social pathologies (Wilson, 1987: 58). However, the residents of high-poverty neighborhoods are quite diverse, and many if not most do not conform to the underclass stereotype (Jargowsky, 1996).

Areas of concentrated disadvantage are referred to by different terms, each with a different set of connotations. In the United States, segregated black neighborhoods are often referred to as *ghettos*, which, according to Wacquant (2004: 2) is constituted of four elements: stigma, constraint, spatial confinement, and institutional encasement. However, the term is disputed and many areas commonly referred to as ghettos do not strictly meet Wacquant's definition (Small, 2008). Poor neighborhoods composed primarily of persons of Hispanic descent are called *barrios* (Moore and Pinderhughes, 1993). Another term used to describe concentrated disadvantage is *slum*, which is "characterized by overcrowding, poor or informal housing, inadequate access to safe water and sanitation, and insecurity of tenure" (Davis, 2006: 23; Forman, 1971). In other nations, a variety of different terms are used,

such as favelas, banlieues, shantytowns, etc., and these terms cannot be assumed to be equivalent in either form or function (Hutchison and Haynes, 2012).

Examples of Areas of Concentrated Disadvantage around the World

In 'Planet of Slums', Mike Davis (2006) discusses the history of slums internationally, where "classic [Nineteenth Century] slums were notoriously parochial and picturesquely local places…characterized by an amalgam of dilapidated housing, overcrowding, disease, poverty, and vice" (22). He argues that the British empire in the colonization period contributed greatly to slums in the Third World, calling the British "the greatest slum-builders of all time" (52). Ostensibly, their policies in Africa forced the local labor force to "live in precarious shantytowns on the fringes of segregated and restricted cities" (52). Similarly, they provided minimal infrastructure to native neighborhoods in India, Burma, and Ceylon, which increased death tolls related to disease outbreaks such as cholera and plague. Davis asserts that state-assisted housing in the Third World is for the most part detrimental to health and safety because public services are lacking (69).

Slums have been growing since the 1970s. In fact, most urban poor now live in slum communities on the periphery of cities in developing countries (Drakakis-Smith, 2012a: 99), in edge developments that are either squatter settlements or pirate subdivisions, both generating a shantytown landscape (Davis, 2006: 37–38). With "more than 200 000 slums on earth, ranging in population from a few hundred to more than a million people" (37), "Megaslums arise when shanty-towns and squatter communities merge in continuous belts of informal housing and poverty, usually on the urban periphery" (Davis, 2006: 26). Examples include barrios in Mexico City, Mexico; condos in Lima, Peru; kampungs in Jakarta, Indonesia, and Kuala Lumpur, Malaysia; and slums in Nairobi, Africa, Cairo, Egypt, and countless cities in developing countries across the world (27). The world's highest percentage (62% of the urban population) of slum dwellers is in sub-Saharan Africa, Sierra Leone, Sudan, and the Central African Republic (UN-Habitat, 2013), Ethiopia, Chad, Afghanistan, Nepal, Bombay, Mexico City, Dhaka, Lagos, Cairo, Karachi, Kinshasa-Brazzaville, Sao Paulo, Shanghai, and Delhi. In Bombay, for instance, there are an estimated 10–12 million squatters and tenement dwellers, (Davis, 2006: 23). Millions of people live in substandard settlements 'concentrated' in each of these cities. "The fastest growing slums are in the Russian Federation and the former Soviet republics" (Davis, 2006: 24, referencing e.g., 2003 UN-HABITAT case-studies).

Areas of concentrated disadvantage have taken various forms in different parts of the world such as primitive dwellings (e.g., Mexico City), favelas (e.g., Rio, Sao Paulo), illegal slums in Beijing where rural migrants live in crowded conditions, sprawling squatter settlements in South Asia, Indian slums in Mumbai and New Delhi, fetid slums in Nairobi and Mombasa, and areas in sub-Saharan Africa where hundreds of millions of slum dwellers live devoid of universal primary education and with high infant mortality rates (Davis, 2006: 16–19). Other examples are over-crowded rooms that the poor rent in inner-city tenements in Sao Paulo, mostly prior to the favela boom of the 1980s (Davis, 2006: 34).

There is great variation in the type of dwellings people inhabit in areas of concentrated disadvantage. The *chwals* of Mumbai, according to Davis (2006), are "mostly dilapidated, one-room rental dwelling that crams a household of six people into 15 square meters" (34). Clusters of the *jhuggi-jhonpri* (hutment) squatter settlements that are inhabited by an estimated 3 million (or one-third) of New Delhi's population are typically constructed out of mud, brick, and tin-thatched roofs and are often located right next to five-star hotels or modern high-rise buildings (Dupont et al., 2000). The *callejones* of Lima that are built to be rented by the poor are unstable, substandard dwellings. Thousands of squatters live in abandoned buildings and factories of Buenos Aires. Other examples include roof dwellers in Cairo and boat dwellers (floating slums) in Southeast Asia (Davis, 2006: 34–36). Squatters are the "pioneer settlers of swamps, floodplains, volcano slopes, unstable hillsides, rubbish mountains, chemical dumps, railroad sidings, and desert fringes" (Davis, 2006: 121). Over half of Johannesburg's nonwhite population dwells on "dangerous, unstable dolomitic soil contaminated by generations of mining" (Davis, 2006: 122). Similarly, the soil upon which the favelas of Sao Paulo and Rio de Janeiro, Caracas, or Manila are built is unsuitable for squatter settlements because of its flood plains.

Urban slums around the world have proliferated in conjunction with rapid urbanization in areas least able to cope with the rise in population. According to the 2009 UN Habitat Global Report on Human Settlements (UN Habitat, 2009), for the first time in history, most of the world's population lived in cities in 2008, and the majority and almost all of new global population growth is predicted to occur in cities and in the global South. With the rise of migrants in slum and squatter districts who often settle in cheap, substandard housing (Drakakis-Smith, 2012b: 16), a rise in urban concentrations of poverty and inequality is predicted and will likely exceed the 32% of the world's urban population (924 million people in 2001) that lives in slums on extremely low incomes (UN Habitat, 2009: 2263).

Marx et al. (2013) point out that contemporary slums of the developing world may constitute 'poverty traps' and 'policy traps' (Marx et al., 2013). Their argument is based on historical and contemporary facts such as surveys collected in slums of Bangladesh, India, Kenya, and Sierra Leone, as well as extensive fieldwork of the Kibera slum in Nairobi. Their findings suggest that slums have often been inhabited by several generations, and as such may constitute 'poverty traps', with it bringing a host of associated disadvantages. For example, slums lack public and private investment, and since housing is non-permanent and tenants have no ownership over the land, they are not incentivized to improve their living conditions. As a result, as more and more people settle into these substandard dwelling areas, overcrowding causes health and sanitation issues and potentially disease outbreaks.

Although slum dwelling has been characterized as intergenerational, slums continue to expand based on rural migration. Regardless, the economic and social mobility of slum dwellers is undermined by high rents to live in close proximity to the city. Ironically, urban slum dwellers often fare worse

than their rural counterparts, as the former have a higher rent burden than their rural counterparts who often do not pay rent. Failing governance, corruption, and otherwise inefficient allocation mechanisms frequently leave room for 'slumlords', local chiefs, gangs, or drug cartels to manage and control the area and financially exploit residents. To be sure, slums are areas of concentrated disadvantage and according to Marx et al. (2013) often pose a 'policy trap' (Marx et al., 2013). Indeed, slum neighborhoods exist 'in the margins' and typically do not receive public investment such as urban planning or economic development. In addition, slum populations are rarely captured by the census that leads to undersampling and other statistical problems that obfuscate reality and make even potential policy interventions difficult.

Concentration of Poverty in the United States

Neighborhoods in which more than 40% of the population have incomes below the federal poverty line are characterized by high rates of single parenthood, low levels of educational attainment, and detachment from the labor force (Jargowsky, 1996). Further, the lack of opportunities and role models in such neighborhoods contributes to a social milieu in which alcohol and drug abuse, gang membership, criminality, and other self-defeating behaviors become more prevalent (Wilson, 1987, 1996). Thus, a good measure of the concentration of the poverty is the percentage of the poor in a given area that lives in neighborhoods, defined as census tracts (Census tracts are small geographic units delineated by the US Census Bureau that contain 4000 persons on average (White, 1987).), in which 40% or more of the population is classified as poor according to the US federal poverty line (Jargowsky and Bane, 1991). (As of 2014, the federal poverty line is $24 000 per year for a family of four (Department of Health and Human Services, 2014).)

By this measure, the concentration of poverty rose dramatically during the 1970s and 1980s (Jargowsky and Bane, 1991; Jargowsky, 1997; Kasarda, 1993). The increases were fastest in the Midwest and Northeast, areas that suffered from rapid deindustrialization and rising poverty. In fact, concentration of poverty is closely correlated with overall economic conditions at the metropolitan level. Not surprisingly, therefore, the concentration of poverty declined substantially during the 1990s, a decade of rapid economic growth and low unemployment (Jargowsky, 2003; Kingsley and Pettit, 2003). The number of high-poverty census tracts – those with poverty rates of 40% or more – fell 26.5%, from 3417 in 1990 to 2510 in 2000 (Jargowsky, 2003).

Since 2000, the spatial concentration of poverty has surged again. (The results presented here draw heavily on Jargowsky (2013, 2014b).) The count of high-poverty census tracts increased by 800 (32%) between 2000 and the 2005–09 American Community Survey data to nearly the level of 1990, even though these data span more than 3 years before the financial crisis hit in late 2008. The latest data, spanning 2008–12, show that the number of high-poverty tracts has increased to 4054, a 62% since 2000 (Jargowsky, 2014b). The number of people living in high-poverty neighborhoods – census tracts with poverty rates of 40% or more – increased from 7.1 to 12.4 million, a 72% since 2000.

The racial/ethnic composition of the population of high-poverty neighborhoods has changed due to different rates of growth in among demographic subgroups. For example, while the population in high-poverty neighborhoods has risen for all racial and ethnic groups, it has grown fastest among non-Hispanic whites; the count of whites in high-poverty areas more than doubled, increasing 122% between 2000 and the most recent data. In comparison, the black and Hispanic population of those areas increased 51 and 74%, respectively. As a result, whites now make up 26% of the population of high-poverty tracts, compared to 20% in 2000. The black population share has declined from 42% in 2000 to 37% in 2008–12. The Hispanic share has remained constant at approximately 31%.

While the number of high-poverty neighborhoods has risen, it is also true that the number of poor persons has risen overall, both due to population growth and the general rise in the poverty rate since 2000. To ask whether poverty is more concentrated, we must examine the percentage of the poor living in high-poverty areas. In the average metropolitan area, the percentage of the poor living in high-poverty neighborhoods rose from 11.6 to 15% between the 2000 and 2008–12 period, although the concentration of poverty is still lower than that in 1990, when it was 16.8%. It rose for all groups, though the increase was fastest for whites – rising from 5.1 to 8.4%. Despite the recent increase in whites living in high-poverty areas, concentration of poverty still differentially affects members of minority groups. The black poor are nearly three times more likely than the white poor to live in high-poverty neighborhoods, 24.6% compared to 8.4%. The Hispanic poor are twice as likely as the white poor to be in neighborhoods of concentrated poverty.

Causes of the Concentration of Disadvantage

One of main causes of the concentration of poverty in urban centers in the United States is deindustrialization, which eroded the historic job base of many older industrial cities (Bluestone and Harrison, 1982; Gillette, 2011). Ironically, deindustrialization occurred just after a wave of building large-scale public housing projects, which anchored to the poor to areas where jobs for less well-educated workers were becoming nonexistent (Venkatesh, 2002).

Another important factor in the creation of high-poverty neighborhoods was the vast outmigration to the suburbs that began after World War II and accelerated in the 1960s when urban riots, violent crime, and racial tensions came to the fore (Mieskowski and Mills, 1993; Massey and Denton, 1988). Two factors are key to understanding the effect of the suburban explosion on central cities. First, suburban growth produced housing units much faster than needed to accommodate metropolitan population growth. Between 1970 and 1990, for example, most large central cities and some older inner-ring lost population rapidly, while successive new suburban rings gained population (Jargowsky, 2002). Second, zoning was used to prevent low-income persons and racial minorities from leaving the confines of the central city (Galster, 2012; Fischel, 2004). In effect, while discrimination on the basis of race is strictly illegal,

discrimination on the basis of income, through exclusionary zoning, is the law of the land. The result is selective outmigration, segregation by race and class, depopulation of the inner city and older suburbs, and concentration of poverty. In additions to limits on mobility, racial and class differences in neighborhood choice patterns tend to reinforce and sustain existing segregated patterns (Sampson and Sharkey, 2008).

In other nations, the causal sequence can be quite different. Some of the main contributing forces to slum expansion around the world are the rapid rate of rural to urban migration due to industrialization, the lack of neighborhood planning, and overpopulation in general (Henderson, 2010; UN Habitat, 2009). Most slum dwellers are rural residents who migrated to cities in search of employment opportunities, education for their children, and improved health and social services. The kinds of jobs that migrants seek are in manufacturing and the service sector. Although urbanization and economic development are intertwined, they are not causally related. Rapid urbanization does not necessarily lead to per capita income growth (Henderson, 2010). As a result, migrants looking for work and improvement in quality of life who move to the urban areas may wind up in similar or worse conditions of poverty then where they left.

Consequences of the Concentration of Disadvantage

Areas of concentrated disadvantage where people are subjected to adverse economic and physical conditions have negative effects on their residents, and there are also larger societal costs associated with slums. Nunes and Veloso (2012) write that the Brazilian favelas in Rio de Janeiro and other large cities "arose as a marginal space where economically and socially excluded individuals gathered – a function that has changed very little" (Hutchison and Haynes, 2012). Exclusion, it would seem, is dangerous when coupled with inequality. Gilbert (2012) points out that inequality has increased in Latin American cities where the institutions create a second-class citizenship status for the poor, and "the education that you get marks you for life, determining your occupational possibilities" (quoting Roberts, 2004: 196 in Hutchison and Haynes (2012: 212)).

Aside from the unsafe conditions of these settlements based on local geological and climatic hazards, these communities are undesirable places to live for a variety of reasons. As such, they are often marked by alcohol stores, litter, stagnant water, open sewage, etc. Such adversity often has detrimental effects. For instance, in refugee camps of Gaza and Zaire, the substandard sanitary conditions lead to cholera and other disease outbreaks. Not surprisingly, infant mortality rates are often much higher in unsanitary living areas.

Social segregation is accentuated through inequality, and rich areas are segregated from poor ones, for example, in Bogota, Rio de Janeiro, Caracas, Santiago, etc. creating spatial barriers also through gated communities. There has been a historical division into a 'two-class' society in which the well-off children attend private institutions and elite private recreational clubs. Gilbert (2012) argues that there is a different cultural, historical context in Latin America where the rich are spatially segregated (e.g., gated communities); however, settlements inhabited by the poor are not necessarily cut off from contextual educational and employment opportunities.

Relating to spatial segregation in France, Castañeda (2012) points out that the banlieues at the outskirts of Paris are comparable with the US ghettos in that they have produced a ghetto subculture inclusive of French rap and youth slang; are home to immigrants; and are marked by high unemployment rates, violence, lacking social integration and equality, and segregated, much like black ghettos in the United States (Castañeda, 2012: 177–179). He argues that relative deprivation is most important for people in ghettos and banlieues, and "long-lasting ethnic segregation is not voluntary but imposed from the outside" (Castañeda, 2012: 184).

The question of whether poor neighborhoods have independent effects on residents has been extensively studied in the United States, with mixed results (Duncan et al., 1997). Low-income neighborhoods have lower levels of education, employment, and earnings and higher rates of poverty, single-parent families, and other social problems. However, these characteristics may be compositional rather than causal; in other words, people with those characteristics may migrate into high-poverty areas to obtain cheap housing, or people who lack those characteristics may move out (Tienda, 1991). The question is whether these concentrations of poverty have negative effects on social and economic outcomes after controlling for individual and family traits. Increasing evidence suggests that it does have negative effects, particularly when studies take into account long-term and multigenerational exposure to disadvantage neighborhood contexts (Sampson et al., 2008; Sharkey and Elwert, 2011).

Concentration of disadvantage has implications for educational outcomes because schools are creatures of neighborhoods (Levy, 1995). Often, the relationship is legally encoded in school attendance zone boundaries. Even schools that draw on larger and less precise areas, such as magnet and charter schools, commuting time and transportation costs often restrict attendance to those who live relatively nearby. Schools usually closely reflect the racial and economic composition of the surrounding community. When they do differ, public schools will tend to have a greater proportion of minority and low-income children, due to life-cycle differences and differential selection into private schools and home schooling. Thus, schools are often even more segregated by race and income than is the surrounding community (Rivkin, 1994; Jargowsky, 2014a).

As a result, when poor families reside in different neighborhoods than middle- and upper-income families, their children will likely attend different schools than more affluent children. Over time, the schools themselves can become different. Schools in poorer neighborhoods have greater needs than schools with more advantaged children. Teachers and school administrators may develop lower academic expectations when they deal predominantly with poor children, many of whom who do not have resources or support in the home (Farkas, 1996). In some inner-city schools, working hard and getting good grades is derided as 'acting white' (Fordham and Ogbu, 1986; Fryer and Torelli, 2010). Even students who resist caving in to peer pressure

may still be impeded in learning if enough classmates are disruptive and slow the pace of instruction. These so-called peer effects on students have been documented in a number of carefully controlled studies (Hanushek et al., 2003; Summers and Wolfe, 1977; Zimmer and Toma, 2000). Over and above peer effects, neighborhood conditions have spillover effects on academic achievement (Crane, 1991; Crowder and South, 2003; Datcher, 1982; Jargowsky and El Komi, 2011).

A variety of studies have found that neighborhoods matter for child and adolescent development across a variety of developmental outcomes (Leventhal and Brooks-Gunn, 2000). For example, a child's IQ at 36 months of age is related to the presence of affluent families in the child's neighborhood after controlling for family income, mother's education, family structure, and race (Brooks-Gunn et al., 1993: Table 2). Children raised in families exposed to high-poverty neighborhoods for two consecutive generations score more than half a standard deviation lower on measures of cognitive ability, even after controlling for a wide range of family and individual characteristics (Sharkey and Elwert, 2011). Girls with fewer affluent neighbors initiated sexual activity earlier and were more likely to have out-of-wedlock birth, again controlling for family characteristics (Brooks-Gunn et al., 1993; Browning et al., 2004; Crane, 1991). Children with a high proportion of poor neighbors have more behavioral problems, lower self-esteem, and more symptoms of depression (Chase-Lansdale and Gordon, 1996; Chase-Lansdale et al., 1997). The Project on Human Development in Chicago Neighborhoods found that exposure to nearby homicides has an immediate and substantial effect on children's performance reading and vocabulary assessment (Sharkey, 2010).

The concentration of poverty often makes for an unhealthy environment with few parks and recreational resources, greater pollution, more alcohol outlets, more advertising for alcohol and tobacco, and less availability of healthy foods (Barbeau et al., 2005; Gordon-Larsen et al., 2006; Hackbarth et al., 2001; Lopez and Hynes, 2006; Wolch et al., 2005). Residents of disadvantaged neighborhoods suffer higher rates of communicable diseases such as tuberculosis (Acevedo-Garcia, 2000), premature birth (Osypuk and Acevedo-Garcia, 2008), self-report of poor health (Subramanian et al., 2005), diabetes (Ludwig et al., 2011), and obesity (Lopez and Hynes, 2006; Ludwig et al., 2011). Residence in economically and socially isolated census tracts increases the probability that adolescents will engage in health-risk behaviors (Frank and Bjornstrom, 2011; Frank et al., 2007).

Conclusion

Concentration of disadvantage, concentration of poverty, and related concepts are ways of thinking about the spatial dimension of disadvantage. The key insight is that the problems of poverty and other social disadvantages are magnified when disadvantage is clustered at the neighborhood level. Indeed, many of the problems associated with poverty – exposure to crime and violence, failing schools, dilapidated housing – are actually neighborhood characteristics. Hence, the study of poverty and disadvantage would be incomplete without consideration of concentration and its effects.

Concept Formation in Childhood: Cross-Cultural Perspectives

Dušan Krnel and Darija Skubic, University in Ljubljana, Ljubljana, Slovenia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Described is the concept formation in early age according the latest accepted theories. Emphasis is on the constructivistic view and the role of classification ability in young children. Reviewed are different approaches toward classification and the properties or biases that attract children's attention. Exposed is the role of language and the relationship between thought and speech in concept formation. Cultural diversity is introduced with two examples: on the construction of the concept of time and on the construction of the concept of space.

Concept Formation

Alongside other knowledge related to 'disparate areas of the mind' are theories about concept formation that are slowly constructing a more coherent picture. As a result, even today one finds entirely contrary theories in the larger discourse, from nativism (Fodor, 1975, 1981) to models constructed upon the theory of cognitive development and constructivism. Nevertheless, there is some general agreement that concept formation is closely connected with cognitive growth; therefore, one of the stronger lines in developing a model of concept formation begins with J. Piaget. According to Piaget (Inhelder and Piaget, 1964), the process of classification or 'what things belong together' seems to play a role in every intellectual function – especially concept formation. After his first report in the 1930s, numerous studies followed regarding how children of different ages, genders, and social groups classified different objects and their argumentation for so doing (Reichard et al., 1944; Welch and Long, 1940; Sigel, 1953; Silverstein, 1960; Elkind, 1961, and many others). The classification process also proved intriguing for the behaviorist. While constructivists described these acts in logical-mathematical terms of extensivity and intensivity of the class of the object, and everything in the mind being derived from concrete actions, the behaviorist described classification and concept formation in terms of classes of stimuli or stimulus complexes (Lunzer, 1979). If one simplifies this role of classification in the process of concept formation – whatever the constructivist or behavioristic approach – the process can be described as follows: differentiation between the properties of objects in a given set, followed by discrimination between properties that are specific to an object and those that are common to the set; and finally, the identification of common properties, which then leads to the development of new concepts (Lovell, 1971). At the end of the process comes the label for this class, and this, according to Piaget, is the word (Labinowicz, 1989).

But for many psychologists, philosophers, and linguists, this view was over simplified and diminished the role of language. It was Lev Vygostky who, from the constructivist point of view, better elaborated the relation between thought and speech in the process of cognitive growth and concept formation.

The Role of Mental Operations

Let us first examine the Piagetian view of concept development as can be interpreted after all the modifications, criticism, and improvements his theory underwent. In new encounters with an object, the child classifies the object into a class that has already been generated. In this way, the new object can be assimilated into the existing structure. Alternatively, an encounter with a new object may not fit precisely with or into existing classes and may require a process of accommodation in which the characteristics of an existing class are modified, thus bringing about conceptual change (Labinowicz, 1989). Children use numerous ways to classify objects and ideas. Inhelder and Piaget (1964) identified 'graphic' and 'spatial' collections. Another route is the 'thematic' collection, whereby children group objects by telling stories about them; or the 'complex structure,' where objects are linked by an idea. Often, one also encounters collections of pairs – groups of two objects that match in some way; and 'chain connections' see new connections found between each new pair in the chain; as well as classification by association and still other means (Bruner et al., 1967). The research work of Nguyen and Murphy (2003) addresses multiple forms of conceptual organization. They have criticized the view that exposed only the taxonomic categorization in concept development and treated other types of categorization as primitive. They argue that adults too use thematic and script categories when certain relations are sufficiently strong. Their results showed that preschool children could selectively use different classification strategies.

Rosch (1980) proposed the 'prototype' model – a quick and effective method of classification made possible by comparing an object with a prototype. Prototypes are seen as an example of a group with typical characteristics. The consequence of this strategy is the differentiation of objects of the same category at different levels – those more central or closer to the stereotype. This differentiation method is central to many models in cognitive science. According to Rosch, so-called natural categories of objects are formed around prototypes. Those that belong to this category share not only certain perceptual similarities but also similar sensorimotor actions.

A characteristic of the natural category 'chair' is a flat surface – but also the 'action' of bending one's knees.

The constructivists in psychology hold that an infant's knowledge is contained in schemata and sensorimotor functions. A schema is defined as the representation of the patterned perceptual feature of an event, and need not possess a semantic component or an inference as to its origin (Kagan, 2008). The primary feature of an object is spatial extent, shape, color, contrast, motion, symmetry, angularity, circularity, and density of contour. The origin of classification and seriation are to be found in sensorimotor schemata; later these schemata are internalized and become one of the mental processes (Inhelder and Piaget, 1964).

The role of action in concept formation was studied by Ogborn and Bliss (1990) and Bliss and Ogborn (1994). Their model was used for the development of the concept of 'movement' (the psycho-logic of motion). A similar model was proposed by Krnel et al. (1998) with respect to the concept of matter.

In order to understand the concept of matter, primitive actions (e.g., to hold, to grasp, and to move) are necessary. Combinations of these actions are used to evolve prototypes. Primitive actions may also be integrated into schemata and are further upgraded into primitive laws (e.g., parts move together with the whole object, or movement can be triggered upon touch). Primitive actions, prototypes, schemata, and laws may be used by children to develop hypotheses about a number of concepts. Although derived from action, the function of an object or function of the category of objects (what they are used for) as criteria for classification appear later. The study of Horst et al. (2005) notes that from an early age, infants form appearance-based (where shape is one of the dominant properties) categories before the functional-based, and that this preference continues during the time they are learning the names of objects, between the ages of 2 and 4 years. Regarding the relationship between function and action, Perone and Oakes (2006) noted the important role of two features of infantile perception: infants can perceive a stimulus event that involves function as causal event; or they perceive, e.g., hands acting on objects as goal-directed agents.

Another model describing mental entities was proposed by di Sessa. He introduced the phenomenological primitives or p-prims. P-prims are small knowledge structures accepted intuitively as self-consistent explanatory facts. In some cases, they become the intuitive equivalent of physical laws, explaining other phenomena but themselves remaining unexplained (di Sessa, 1983). P-prims are based on experience, they do not represent a coherent system – and they may even stand in contradiction to one another. The most common example in literature for p-prims is heaviness. For children, heaviness is an intrinsic property of an object.

But these p-prims also have their own origin. Being based on experience means that some of them, e.g., heaviness, are developed from primitive actions like to hold, to move, or, more generally, from actions where children really feel the force of weight on various limbs or muscles.

In their work to determine how primitive concepts or natural kind concepts might be acquired, Laurence and Margolis (2002) introduced the kind syndrome. "The kind syndrome is a collection of properties that is highly indicative of a kind yet is accessible in perceptual encounters." Laurence and Margolis studied a number of different psycholinguistic experiments where researchers had discovered a number of important biases that enabled concept acquisition. For them, the central (research) question was how do children learn the meaning of a word when they are faced with an object displaying so many properties? How could a child know whether the word 'cup' referred to the color of the cup, the contents of the cup, to a particular situation, or any number of other possibilities? They found that one of the important biases is shape. Beginning with shape and other important biases together with an understanding of their relative importance enables children to represent kind syndrome.

But in many cases this is not enough. An object may appear just like the real or genuine object, but it can also be a fake. How are even young children able to recognize it as a fake? One of the answers to this question emerges from studies about the development of the concept of living (Carey, 1985). In these studies, it was found that children are able to recognize and verbalize some crucial processes and properties (feeding, growth, etc.); and recent studies support previous findings (Jipson and Gelman, 2007). Margett and Witherington (2011) discovered both competence and confusion in preschoolers' living kinds conceptualization, and suggested that this period marks the beginning of an abstract, biologically organized framework.

Another way of answering the question of young children's ability to distinguish between fake and real objects is essentialist tendency (Laurence and Margolis, 2002). When acquiring primitive concepts, children start out with a predisposition toward psychological essentialism. After an experience with a new object, new information is accumulated and linked to the existing mental presentation. In this way, this storing comes to compose a kind syndrome. Finally, the kind syndrome and the essentialist disposition together lead the inference of new representation.

Psychological essentialism is the idea that certain categories, such as 'living' or 'female,' have an underlying reality that cannot be observed directly. There is also evidence that psychological essentialism is an early cognitive bias. The ideas of essentialism see in young children the tendency to go or dig deeper, in search of a nonperceptive feature, which stands in opposition to the standard view of children as concrete thinkers (Taylor et al., 2009).

There are also interesting debates about the role and relation between perceptual and conceptual categorization. According to the theory of constructivism, concepts form a network, which as children mature become increasingly complex. Many constructivists see the process of learning as a process of differentiation between concepts and as a process of developing firm relations between concepts in this structure. Under the influence of the work of Piaget D.P. Ausubel (1968), assimilation theory and the concept of meaningful learning developed. Ausubel stressed the importance of prior knowledge or cognitive structures that should be prepared for bonding new concepts. Thus, if a child could not connect a new concept into an existing structure, the

assimilation failed and the new concept would remain without proper meaning. Through his theory of meaningful learning, Ausubel exposed the role of advance organizers. Advance organizers can be treated as devices used in the introduction of a new concept, which enable learners to orient themselves and to locate where a concept fits in and how it links with existing cognitive structure. Following D.P. Ausubel, J.D. Novak (1990) introduced the technique of concept mapping. Novak did impressive work with children as young as 6 years old making concept maps to represent their response to focus questions such as 'What is water?' and so on.

Using a hierarchically organized model of cognitive structure then raises the question of how the process of organization of concepts in a hierarchical order actually runs. Ausubel (1978) proposed three ways: subordinate learning (new information is linked under a superordinate concept), superordinate learning (existing concepts are recognized as more specific than the new one), and combinatorial learning (the new concept is on the same level as existing related concepts). Children spontaneously assimilate new concepts in all three ways.

In the process of learning, concepts move in their hierarchy not only vertically but in some cases also horizontally, from one bunch of concepts to another. This shift is well explained in the model of the ontological tree developed by Chi (1992). She suggested that there are fundamentally distinct conceptual trees for different ontological categories, for example, category of matter, category of processes, and category of mental states. Young children classify according to their psychological ontology; the concept of heat, for example, is classified in the same branch as material substances. In the process of adequate learning, it is possible to move 'heat' from the material branch to the processes branch, which is an appropriate classification. Chi argues that scientific concepts are difficult to learn if they have an ontological status different from their own initial classification.

The Role of Language

Vygotsky (1986) and Piaget (1962) place the developmental stage of thinking to entirely different developmental levels. Piaget considers this stage a transitional level from unconscious thinking to the logical, from the intimate-individual to the social. Vygotsky, however, offers that it is a transitional form, from the external to the internal, from the social to individual speech, including unconscious speech thinking.

According to Vigotsky's theory, a word is regarded as embodying a concept; therefore, the child uses a word for communication purposes before the child fully understands that word. In function, words are a means of focusing attention, selecting, analyzing, and synthesizing distinctive features in the process of concept formation. In Vigotsky's view, a child does not choose the meaning of his or her words, the meaning of the words is given to him in his conversation with adults; therefore, a child does not spontaneously develop concepts independent of the meaning that word has in a social environment. The meaning of a concept expressed by words is imposed upon the child and is not assimilated in ready-made, but is instead a process of constant development while the child is in communication with adults. Vygotsky claimed that two different preconceptual stages occur in early childhood: the syncretic heap stage and the complex stage. In the first stage, the child groups together objects or ideas that are objectively unrelated. In the next complex stage, the child begins to abstract different attributes about the ideas or objects, and starts to organize ideas into groups. These complexes are determined by the meaning of a given word from the language of adults.

With their ideas and their research in psychology and linguistics, Piaget and Vygotsky encouraged the development of a number of directions, looking for a theoretical explanation of the relationship between thought and speech. Some philosophers claim that it is conceptually necessary that all thought depends on language; other philosophers claim that all thought is, not only conceptually, but also metaphysically and causally, independent of natural language. Between these two poles is a multitude of plausible claims that most, some, or specific types of thought depend on natural language conceptually, metaphysically, or causally. There are many thoughts that one would never have thought in the absence of language.

To clarify these two theories, it is necessary to differentiate between schemata and semantic forms. A schematic prototype can exist without any support from semantic elements. A number of research projects demonstrate that infants under 8 months display reactions to events that are different from those expected, and that understanding these does not require any semantic representation (Kagan, 2008). Only semantic forms posses the semilogical relations that take the form of hierarchically ordered categories for objects and events. Therefore, speaking about concept structures, hierarchical organization, subsuming and superordinate learning, concept mapping, and other processes proposed by Ausubel and Novak imply semantic elements; and these relations emerge only after 5 or 6 years of age.

The relationship between semantic and biases (schemata) is well illustrated in the research of Yoshida and Smith (2003). They proved the hypothesis that names direct attention at two levels of abstraction: known names direct attraction toward the properties most relevant to the category and novel names direct attraction to the shape of objects. In this intercultural study, the object was presented to a child, its name was told, and asked which one of the three alternatives was called by the same name. In the second experiment, known names were replaced with novel, invented ones. The results showed that English- and Japanese-speaking children – in this specific situation – formed categories organized by shape.

In the same context of biases (shape bias in particular) and names, Diesendruck and Bloom (2003) argue that many tiny details influenced children's responses. They concluded that children use not only shape bias, but also appearance (schemata), as adults do. "Something which looks like a dog is likely to be called dog." They concluded that generally, children treat names as referring to kinds.

Two researchers who followed Vigotsky's idea were Diaz and Berk, who studied the self-directed verbalizations of young children during problem-solving activities. They found that children verbalized more when the tasks were

more difficult, and that children who verbalized more often were more successful in their problem solving.

Experts do allow for the possibility that certain types of thought depend on language, at least to the extent to which language is needed, or language is (*de facto*) the cause of their existence. The aim of many researches was to find a causal role for language in the acquisition of kind concepts. Perner et al. (1994) argued that, in the least instance, the use of language enhanced one's capacity for mind reading. Furthermore, Peterson and Siegal (1995) claimed that deaf children, who were late in their acquisition of language also showed a corresponding delayed capacity for mind reading. However, the existing data are consistent with the view of mental-state concepts as an innately structured mind-reading faculty.

Regardless of certain central theories about language and its relation to the thought process, relatively recent research supports the hypothesis that infants learn their first words differently than older children. The study of Pruden et al. (2006) suggested that the process of learning words undergoes a developmental shift. Infants at 10 months can learn new labels by relying on perceptual salient properties instead of social cues provided by a speaker. The latter process or approach is characteristic for older children of 12, 18, and 24 months.

A special case regarding the relationship between thought and language is the acquisition of the concept of number. There is considerable evidence that some numerical concepts exist independent of language (Xu and Spelke, 2000). Children in the preverbal (prior to forming words) period (6 months) can approximately assess a number. Similarly, they can roughly assess the size of the set/series and recognize that a particular set is bigger/smaller than the other. Older children are better at differentiating numbers than the younger, but this also depends on the size of the described lot, as differentiation becomes more difficult as the series increases in size. Moreover, some animals carry out simple calculations using approximate numerical representations. For example, they can calculate the average speed/distance (rate) of their return from the source of food. Other researchers have further argued that animals and children have the ability to accurately understand small numbers and to compare up to three or four numbers (Whynn, 1992; Deahaene, 1997). For example, children who see two objects behind a screen (canvas, curtain) will be surprised if either only a single object or three objects instead of the (anticipated) two are displayed when the screen is raised. Such understanding is clearly numerical, as it does not depend on the identity or properties of these objects.

As regards research with infants, it is worth noting certain methodological problems well explored by Kagan (2008). He demonstrates that many researchers ignore factors that can influence the duration of attention to an event, which is the main diagnosis indicator. These factors are the curvilinear relation between unfamiliarity and the duration of looking, the influence of brain maturation, and the significance of the physical features of the stimuli. Kagan therefore inferred that many facts are inconsistent with the hypothesis that infants' reactions to visual displays varying in number are a sign of competences that are similar to older children's concept of number.

When discussing exact numerical concepts for numbers that are greater than 4 (5, 6, 7, 64, 5 million, etc.), most researchers believe that their acquisition depends on language, especially on mastering the list of 'word count' (5, 6, 7, 8, etc.) and counting procedures. In this case, the whole class of concepts is language-dependent. But there is still an ongoing debate on the manner in which the acquisition process should appear. Some researchers have argued that the basic process includes planning the list/file of counting prior to the preexisting approximate numerical system (Whynn, 1992); others, however, have offered that children themselves find their way to the concept of bigger, exact numbers by underlining the first few items on their counting list with representations in the system of object types, and then making some kind of inductive skip or leap (Carey, 2004; Feigenson et al., 2004).

Thought, Language, and Cultural Diversity

The question – What is the relationship between language and thought? – has intrigued psychologists and philosophers for decades. The discussion essentially began with Worf and Sapir and their radical version of linguistic determinism. Whorf's view has long been abandoned on both theoretical and empirical grounds. Fodor (1975) and Pinker (1994) have argued that the position is conceptually incoherent. Empirical studies have shown that speakers of languages that mark different linguistic distinctions can nevertheless make the same conceptual distinctions. For example, color perception in the Dani (Dugum Dani is a stone-age agrarian population) language is fundamentally similar to ours, even though the Dani language has only two color terms (Rosch, 1975). Rosch and Olivier's (1972) investigations demonstrated that universal patterns of memory confusion over colors were independent of color labeling, and this could be interpreted as supporting to the theory of linguistic relativity. The way one understands language diversity – how languages differ in representing reality– affects one's approach to understanding linguistic relativity, how that diversity affects thought.

Recent research has focused on developing muted versions of the linguistic relativity view. Roberson et al. (2005) expanded on the work of Rosch and Oliver (1972) on the Dani people with a comparable group from Papua, New Guinea, who speak Berinmo, and which has five basic color terms. They found that categorical perception affected both English and Berinmo. It was concluded that possession of linguistic categories facilitated recognition and influenced perceptual judgments. Despite this and other investigations, color has continued to be regarded as a special case of universality, rather than of cultural or linguistic relativity.

Piaget already stated that variation in achieving different cognitive operations could be expected among different cultural groups, and that this could be explained by differences in educational and cultural emphases in the development of certain cognitive skills (Piaget, 1962). But there is scarce evidence related to cultural diversity in terms of obtaining basic cognitive operations. The reason for this lies in the research itself. The great majority of studies were carried out on populations of white, middle-class Western children. The second reason for the limited objectivity of results lies in the using of research instruments that were developed for children from Western cultures.

One of the studies from 2000 (Mwamwenda and Grewal, 2000) on conservation skills among preschool children (aged 5 years) in Umtata in South Africa, found that conservation skills had not been acquired. From a group of 70 children, only 5 were found to be operative on the conservation level. These results are not far from many Western studies. It is also well known – and this was one of the criticisms of Piaget – that results depend on the research instruments employed, and on the context in which they are performed. Kagan (2008) cited a study where an 11-year-old Mayan Indian child living in a small, isolated village in Guatemala, performed as well as Boston children when asked to recognize a large number of photographs. He argued that this is due to schemata they have acquired during their first encounter with pictures. The difference in cognitive ability between Australian Aboriginal and European children was studied by de Lacey (1970). In this study, a sample of very high-contact Aboriginals (children living in closer contact with Europeans and their technology) performed at least as well as white Australian children living in similar environments. Environmental differences (socioeconomic status and similar) were considered to have been a major influence in the performance differences found.

More diversity in concept acquisition that derived from cultural diversity can be observed in the acquisition of some ontological concepts such as time and space.

The Concept of Space and Language/Thought

Worf (1956), like many anthropologists both before and after him, was impressed by a variety of human cultures, whereas as a linguist he enthused over various grammatical forms and modes of conceptualization, demonstrated by different natural languages. Some languages, for instance, do not employ terms to describe 'to the left' and 'to the right,' 'to the south of' or with coordinates that relate to the object, e.g., 'between the river and the sea.' Worf then shows that such differences have significant effects on the cognitive processes for which reason (among others) the English and Dani understand the world very differently.

The results of the research carried out by Li et al. (2002) stand in contrast to some current versions of linguistic relativity. Language communities differ in their stock of reference frames (coordinate systems to reference locations and directions). English typically uses egocentrically defined axes ('left–right'). Other languages like Tseltal lack such a system but use geocentrically defined axes ('north–south'). They asked if the lexical resources available in one's language determined the availability or salience of certain spatial concepts. For example, does a 'left–right' lexical gap translate to a conceptual gap? In three experiments, they compared Tseltal speakers' ability to solve spatial problems requiring an egocentric frame of reference to those requiring a geocentric frame of reference. They found that the Tseltal speakers were above average in solving the egocentric problems, demonstrating that a lexical gap does not necessarily lead to a conceptual gap.

One could therefore expect that language affects the efficiency with which a set of relations is processed, and the easier it is memorized (Levinson, 1996). For example, English abounds in an extensive and frequently used vocabulary for expressing motion (walk, stride, saunter, hop, run, and sprint). English speakers should always be vigilant and encode such features. In Spanish and Greek, for example, movement is expressed by auxiliary phrases ('He went into the room at a run'). One could therefore assume that the speakers of these and similar languages are slower in learning and 'poorer' in memory retention (Slobin, 1996). This thesis was carefully examined in the experimental study by Li et al. (2002), in which they could neither detect nor confirm such effects.

Eric Pederson (1995) says that there are three basic types of distinction between languages in expressing spatial relationships.

The first difference lies in the use of some basic terms. Typically, in the European languages, for example, the terms expressing the front and the rear are used in the same way. The front of the tree is the side that faces the speaker. In contrast, some other languages (e.g., the Hausa language) use a different system, in which the front of the tree is the side that is turned away from the speaker.

The second difference lies in the use of different concepts for describing space. We distinguish between the absolute concept (it is characterized by the terms the North, the South, the East, the West) and the relative concept of space (defined by the terms on/to the left, on/to the right, in front of, at the back of). Most European languages use the relative concept.

The third difference lies in the functional load of the terms listed under the second point. Languages can comprise certain terms, but speakers use them only in different contexts. For spatial orientation (e.g., in the instructions where to go), a typical European speaker would use the terms of the relative system, i.e., to the left, to the right, forward, backward, while the speaker of some other language (e.g., Tamil) would use the terms of the absolute system, i.e., would use to the North, to the South, to the East, to the West. A cross-cultural study in the area of spatial language and cognition in Indonesia (Bali), India, Nepal, and Switzerland was made by Dasen and Mishra (2010). In their study, Dasen and Mishra examined a 'geocentric' system. Their general conclusion is that the development of geocentric spatial language and cognition occurs in a complex ecocultural system, which is adaptive and functional.

Temporal Concept and Language/Thought

The relationship between space and time has long been the subject of philosophical inquiry and psychological experimentation. Two sorts of proposals have emerged, one suggesting a symmetric and the other an asymmetric relationship between space and time in the mind. Observations from the first proposal were synthesized in *A Theory of Magnitude* (Walsh, 2003). According to this theory, space, time, and numbers are all represented in the brain and mind by an analog magnitude system and as such they are symmetrically interrelated. The second, alternative proposal also holds that space, time, and quantity are importantly related, but in a different way. For Lakoff and Johnson, representations (concepts) of time and quantity depend asymmetrically on representations of space. In general, young children use spatial terms earlier than their

temporal counterparts (Clark, 1973); for example, they use here and there to designate points in space before they use now and then for points in time, and produce where questions earlier than when questions.

Piaget (1955) stressed that time and space form an inseparable whole in the child's mind, which suggested a symmetric relationship. The results of Piaget's experiments (on time, motion, and speed) suggested that children might, mistakenly, use spatial information for time more than the other way round. In Piaget's theory, the formation of the concept of time starts from mere surface contact with immediate realities and gradually develops into objective time. In this view, time and space form first a unity and later, children's efforts are directed at differentiation between them (Lovell and Slater, 1960). Piaget argues that the notion of time is intellectual in construction, because duration cannot be perceived.

Cassanto et al. (2010) investigated the relationship between space and time in the developing mind. Native Greek-speaking children watched movies with two animals traveling along parallel paths for different distances or durations. The results showed that for the same stimuli, spatial information influenced temporal judgment more than temporal information influenced spatial judgment. This finding demonstrates a reliable cross-dimensional asymmetry. Kindergarten and elementary school-aged children can ignore irrelevant temporal information when making judgments about space, but they have difficulty ignoring spatial information when making judgments about time.

Like other concepts (e.g., quantity of matter), the concept of time is related to the cognitive operation of conservation. Murray's 2006 study found that the shift from nonconservation to conservation of time occurred between the ages of 8 and 10 years. The development of the concept of time is based on the perception of changes – and one of the omnipresent changes in human history has been weather and the cyclical changes in the moon and the seasons. Therefore, in some languages, the word for time and for weather remains the same (e.g., in Italian – tempo/tempo).

Few researchers, however, stress the existence of components or prerequisites for the acquiring of the concept of time (Kayra-Stuart, 1977). These components are order, simultaneity, and duration, as well as their coordination. The results support the following developmental sequence for the concept of time. First, the main components are understood separately (possibly in the above mentioned order), then they are integrated. Moreover, temporal relations are grasped first on a nonverbal level and later on a linguistic level. The study of Richie and Bickhard (1988) revealed that children have a perceptual experience of duration separate from one derived inferentially from nontemporal knowledge (e.g., start/stop relationships, speed, and distance) and that they can use this perceptual knowledge to judge duration problems. This suggests that the logical concept of time involves the capacity to experience duration perceptually. A similar hypothesis about the possession of a primitive capacity to compare duration was proposed by Berndt and Wood (1974). Levin (1977), in an attempt to construct a general model for the development of time concepts, used three 'types' of time: still time, rotational time, and linear time. Her hypothesis stated that a child's concept of time is basically temporal, but that the construction of the time concept is influenced by various factors, including spatial variables. The understanding of linear time is connected with temporally unidirectional events or 'arrows of time' (Friedman, 2003). In an experiment, children 3.5–6.5 years of age compared forward and reverse playings of events on video. He found that even children 3.5–4.5 years of age recognized the anomaly of the reverse versions of gravity and separation events.

A cross-cultural study on the formation of duration time concept in Chinese and Canadian children revealed that both the tendencies and the age at which concept formation develops are almost the same (Manshu et al., 1987).

Different from these particular studies of time concept acquisition based on concrete events and specific context is the general perception of time, which is culturally dependent.

The Aboriginal concept of time differs from the Judeo-Christian perception of time in that Aboriginal people do not perceive time as an exclusively linear category (i.e., past–present–future) and often place events in a 'circular' time pattern, according to which an individual stands at the center of 'time circles' and events are placed in time according to their relative importance for the individual and his or her respective community, i.e., more important events are perceived as being 'closer in time' (Janca and Bullen, 2003). The concept of time for various African tribes too is different from that in Western cultures. Akiiki (Msumange, 2012) describes time in African thought as phenomenological (existential), organic, cyclical, and sacred. Essentially, it is empirical and delineative, taking events as reference points. It is easily understood through the interaction of phenomena in the universe. Time is sacred and profane, and aims or serves to give meaning to events. It is cyclical, that is, spherically organized, and adds dimension to the line as it proceeds forward, giving past and future shape/dimension, which two are separated by the present. The researchers (Msumange, 2012) of this concept argue that this quite different perception of time wields significant influence over everyday life, even on the economic problems confronting Africa.

Concept Learning and Representation: Models

David R Shanks, University College London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Concept learning describes the process by which experience allows us to partition objects in the world into classes for the purpose of generalization, discrimination, and inference. Formal models of concept learning and categorization make divergent assumptions about knowledge representation (for instance, prototypes, exemplars, and rules). As reviewed here, empirical comparisons of such models have enhanced our understanding of key issues such as the role of selective attention in concept learning, the time course of categorization decisions, and the interpretation of neuroscientific findings.

Concept learning describes the process by which experience allows us to partition objects in the world into classes for the purpose of generalization, discrimination, and inference. When children learn that certain objects are apples and others oranges, their newly acquired knowledge allows them to make informed guesses about new objects they encounter (this is an apple but that is not…), to tell members of these categories apart, and to make decisions that support various actions (this is an apple so I can eat it).

Models of concept learning have adopted one of several contrasting views concerning category representation (see Knowledge Representation). In prototype theories, the concept learning process is assumed to yield an abstract representation corresponding to the central tendency of the category exemplars on each of the dimensions of variation. In exemplar models, the concept is simply the set of mental representations of all the category exemplars that have been previously observed, with each instance assumed to be stored as a separate trace. In decision rule models, the learner is assumed to construct a boundary or rule in psychological space, which partitions it into different category regions. These different perspectives, and some of the evidence supporting each of them, are considered in turn. Next, the role of selective attention in categorization, and the way in which the different models deal with selective attention, is discussed. Evidence that categorization may be controlled by multiple mechanisms is evaluated, and finally the fine-scale dynamics (i.e., time course) and some aspects of the neuropsychology of categorization are reviewed.

Prototype Theories

Prototype theories make a simple assumption about concept representation, namely, that a concept is represented as its 'ideal' or 'average' category exemplar. Thus, representations of specific category exemplars do not influence classification. Numerous forms have been suggested for the (probabilistic) response rule; here, we describe one common example (for other examples, see *Categorization and Similarity Models*). The probability that stimulus i is classified into category J, $P(R_J/S_i)$, is given by

$$P(R_J/S_i) = \frac{b_J s_{iP(J)}}{\sum_K b_K s_{iP(K)}} \quad [1]$$

where $b_J (0 < b_J < 1, \sum b_J = 1)$ represents a bias toward making category response J and $s_{iP(J)}$ is the similarity between exemplar i and the prototype of category J. The model states that classification depends on the similarity between exemplar i and the category J prototype relative to i's similarity to the prototypes of all other categories. Similarity is usually measured with multidimensional scaling methods (*see* Signal Detection Theory).

One piece of evidence supporting prototype models is that a previously unseen prototype may in some circumstances be classified with higher accuracy in the test phase than the actual training stimuli. Moreover, compared to the training stimuli, the prototype may be particularly resistant to forgetting (Homa et al., 1981). Notwithstanding their attractive simplicity, several lines of evidence have been marshaled against prototype models of concept learning, at least within the domain of perceptual classification. Prototype models have often been shown to provide poorer fits than other models to large sets of classification data; they make a number of predictions that have been falsified, and they fail to account for a number of well-established phenomena (see Nosofsky, 1992 for a thorough review).

Exemplar Theories

Although it may seem implausible that classification is mediated by a 'chorus' of category exemplars, there is very substantial body of evidence consistent with the idea that a trace is created in memory for each category member that is observed and that the effects of individual exemplars on later classification are long lasting. For example, judging whether a letter string is a word or a nonword is influenced by a single prior encounter with that string, and this influence can persist for many days and be specific to the exact surface form (e.g., font) of the string (Tenpenny, 1995). The best developed formal exemplar-based model of concept learning is Nosofsky's Generalized Context Model (GCM). In the basic form of the GCM, $P(R_J/S_i)$ is given by the equation

$$P(R_J/S_i) = \frac{b_J \sum_{j \in J} s_{ij}}{\sum_K (b_K \sum_{k \in K} s_{ik})} \quad [2]$$

where s_{ij} is the similarity between exemplars i and j and, as before, b_J represents the bias toward making category response J. The idea is that classification depends on the summed similarity between i and each of the members of category J, relative to i's similarity to the exemplars of all other categories. As in prototype models, similarity is usually measured using multidimensional scaling methods.

A sizable amount of evidence supports exemplar models such as the GCM. These models have been shown not only to provide excellent fits to parametric data sets but also to predict a number of qualitative phenomena. For example, they predict that a previously unseen prototype may in some circumstances be classified with higher accuracy in the test phase than the actual training stimuli, and that classification of test items may sometimes be almost completely unrelated to recognition of the same items.

There is also more direct evidence of preservation of the training exemplars in memory. Thomas (1998) first trained participants in a two-dimensional classification task in which values on the dimensions were highly correlated across exemplars. Next, participants were shown stimuli that possessed only one of the dimensions, together with the appropriate category label, and asked to predict the value of the stimulus on the other dimension. Consistent with exemplar theories, Thomas found that many participants were able to perform this task accurately, predicting values for the missing dimension consistent with the correlation observed across the exemplars during training. This implies that they retained quite detailed information about the conjunctions or correlations of feature values across exemplars. Many theories in which information about specific training exemplars is discarded (e.g., prototype theory) would be unable to account for this finding.

The major difficulties faced by exemplar models are that they do not fully reproduce individual differences in the distributions of responses across test stimuli (Nosofsky et al., 1994) and they do not account for certain base-rate effects in categorization (Nosofsky et al., 1992). We will also see below that some further data obtained by Thomas (1998) are very problematic for exemplar theories.

Recently, models have begun to be developed that view concept learning as a problem of probabilistic inference and that use Bayesian computations to determine the probability that a particular item belongs to a given category. Depending on specific assumptions, such models have been shown to have close connections to both prototype and exemplar models.

Decision-Bound Models

In decision-bound or rule-based models, concepts are represented as regions in psychological space. A rule or boundary demarcates the dividing line between one category and another. In their most general form, decision-bound models can assume any mathematical form for these boundaries, but in practice most researchers have assumed that people can only learn 'simple' boundaries, and have therefore attempted to study the plausibility of special cases in which they are constrained to be linear or quadratic. Another reason for studying these particular forms is that the optimal boundary for discriminating between two bivariate normal distributions is either linear or quadratic, and it is reasonable to speculate that many natural categories are multivariate normal. The theory then assumes that, in a two-category situation, if a stimulus (or, more accurately, the percept of the stimulus) falls on one side of the boundary, the participant assigns it to the corresponding category and if it falls on the other side, it is assigned to the other category. Importantly, the distance of the stimulus from the boundary is assumed to be irrelevant as far as $P(R_J/S_i)$ is concerned. In that sense, categorization is assumed to be deterministic.

Decision-bound models have proved difficult to discriminate empirically from exemplar-based models such as the GCM – indeed, under some circumstances they are formally equivalent (Ashby and Maddox, 1993). Decision-bound models are favored by data from nonnormally distributed categories (Maddox and Ashby, 1993) and by evidence that participants in some circumstances do not retain information about specific training exemplars. One compelling example was obtained by Thomas (1998) in the study described previously. Although many participants in Thomas' study were able to predict one dimension value on the basis of another in stimuli drawn from categories with correlated dimensional values, others were quite unable to do this and instead responded by essentially giving the mean value of the missing dimension, despite the fact that they had learned the initial classification. This strongly suggests that during the course of category learning they had extracted a decision bound and discarded information about the specific training exemplars.

On the other hand, there is rather little evidence, even in one-dimensional perceptual categorization tasks, that participants use all-or-none cutoffs as the decision-bound theory predicts (Kalish and Kruschke, 1997).

Selective Attention in Concept Learning

It has been recognized for many years that concept learning increases the amount of attention paid to stimulus dimensions that are relevant for solving a classification problem and decreases the amount paid to irrelevant ones. Goldstone (1994), for example, found that perceptual discrimination of highly confusable stimuli in a same–different judgment task increased as a result of category learning if the stimuli were assigned to different categories, whereas, at least in some cases, it decreased if the stimuli were assigned to the same category.

In the GCM, this process of selective attention is accommodated by assuming that the similarity between a test item and category exemplars stored in memory is a function of their separation in psychological space, and that this space can be stretched or shrunk (thus altering the similarities) along orthogonal dimensions as a consequence of selective attention. A similar process can be incorporated into prototype theories. Nosofsky and his colleagues (e.g., McKinley and Nosofsky, 1996) have now provided abundant evidence on the one hand that this process of selectively weighting the dimensions of stimulus variation in the generation of category decisions is essential in fitting categorization data within the exemplar-based framework.

On the other hand, decision-bound models have been paradoxically successful at fitting categorization data without

needing to assume an explicit selective attention process. In this theory, the structure of the classification problem affects the placement of the decision boundary, but no additional notion of selective attention to stimulus dimensions is necessary. It is perhaps unclear how decision-bound theories would explain results such as those of Goldstone, which provide direct evidence for changes in the perceived similarities of stimuli as a consequence of category learning, but selective attention does not seem to be required for predicting categorization responses per se.

One possible resolution is based on the distinction between selective attention as a perceptual or as a decisional process. The former sees attention as directly altering the perceptual representation of a stimulus, while the latter assumes that attention operates later in the processing stream, perhaps weighting certain features of the stimulus more heavily than others in making a classification decision. Goldstone's data provide strong support for selective attention affecting the perceptual representation of stimuli, whereas direct evidence for an influence on decisional processes – as assumed in the GCM – is largely lacking. Therefore, there is scope for decision-bound models to dispense with selective attention as a decisional process so long as some provision is made for it to operate perceptually, for example, via changes in the variances of stimulus percepts on the different dimensions. (For further discussion, see Maddox and Ashby, 1998.).

One implication of the idea that selective attention operates by stretching and shrinking orthogonal dimensions in psychological space is that all points on a dimension are affected equally – the stretching/shrinking is uniform across the dimension. Thus, equivalent enhancements or attenuations in discrimination should occur at all points along the dimension. A challenge to this, however, comes from evidence that attentional changes can apply nonuniformly; in other words, discrimination at just one part of a stimulus dimension may be affected by experience. Johansen et al. (2010) presented evidence that the GCM with this sort of feature-specific attention can account for certain patterns of categorization behavior better than the standard version with dimensional attention.

Hybrid Models

An obvious possibility suggested by the evaluation of prototype, exemplar, and decision-bound models is that people can use different categorization strategies in different circumstances, and indeed there is now a wealth of evidence in support of this conjecture. For example, Johnstone and Shanks (2001) asked participants to classify letter strings as either 'grammatical' or 'ungrammatical' after exposing them to strings, all of which were consistent with a complex rule. With incidental training conditions, classification was controlled purely by featural similarity of studied exemplars, but with explicit 'code-breaking' training conditions; classification of exactly the same items was controlled by the complex rule and was unrelated to similarity of studied exemplars. Erickson and Kruschke (1998) review the growing body of evidence for this 'multiple-mechanism' view of category learning and representation. Another hybrid model combines prototype and exemplar representations (Blair and Homa, 2003).

A question that arises is how one might computationally model a multiple-mechanism categorization system, and several attempts have recently been made. Erickson and Kruschke (1998), for example, had some success with a 'mixture-of-experts' model, which incorporates both an exemplar and a decision-bound module. In this model, an adaptive learning rule (see Connectionist Models of Concept Learning) determines the extent to which the final category decision is based on one module or the other, and the weight assigned to each module is an inverse function of the prediction error it generates for that particular classification problem.

Time Course of Classification

An important recent development in the study of category learning and representation is the application of formal models to the fine-scale dynamics – specifically, the time course – of categorization. Until quite recently, research concentrated almost exclusively on categorization probabilities, but new methodological techniques provide researchers with powerful tools for studying more microscopic aspects of the categorization process.

Two rather different proposals have been advanced to extend exemplar models to deal with this issue. One approach (Nosofsky and Palmeri, 1997) is to assume that when an item is presented for classification, a race begins to retrieve exemplars from memory. The time to complete the race depends on how similar the stored exemplars are to the test item. When one race is completed, and an exemplar retrieved, a new race commences, and a classification response is only emitted when a random-walk process is driven to one or another decision barrier. The alternative approach (Lamberts, 2000) is to assume that there is a gradual accumulation of perceptual information about the test stimulus and that similarity to stored exemplars varies during the construction of its representation. On this account, classification at any given moment is governed by eqn [2], but the summed similarity term in that equation is dependent on how much information about the test stimulus has been accumulated.

Proponents of the decision-bound theory have advanced a rather straightforward hypothesis about the time course of categorization, namely, that classification response times depend on distance to the decision bound, with greater distances leading to faster responses.

Attempts to distinguish between these accounts are in their infancy, but each appears to have some merits. Nosofsky and Stanton (2005) provide one attempt to contrast them empirically. Further study of the temporal dynamics of categorization is sure to be a major part of future research.

Neuropsychology of Category Learning and Representation

Neuropsychology raises two important issues concerning models of concept learning. First, there is evidence (albeit controversial) that the mental representations controlling categorization are functionally and neurally distinct from those

accessed in standard 'explicit' tests of memory such as recall and recognition. If this is true, it suggests that models of memory are unlikely to provide any useful input to our understanding of concepts and concept learning. The main piece of evidence is that amnesic patients suffering from anterograde amnesia seem to behave normally in category learning tasks while being profoundly impaired on tests of recall and recognition (e.g., Squire and Knowlton, 1995). For instance, one densely amnesic individual (EP) performed normally in learning to classify dot patterns generated from a prototype, while performing at chance in a recognition test for those patterns. It has been concluded from this that the hippocampus, which controls explicit memory and which is damaged in amnesia, plays no role in category learning.

However, the conclusion that categorization and memory are functionally and neurally disconnected has been questioned on the basis of demonstrations that exemplar models such as the GCM can, just like EP, show dissociations between classification and recognition. In Nosofsky and Zaki's (1998) modeling approach, only a single parameter, the sensitivity parameter, was varied in order to account for a general learning difference between amnesiacs and controls. This parameter represents the ability to discriminate among distinct exemplars stored in memory, an ability that is plausibly reduced in amnesiacs as a result of their deteriorated memory capacity. Nosofsky and Zaki showed that decreasing the value of this parameter reduced classification performance only slightly, but reduced recognition performance considerably. Thus, the GCM successfully accounts for the dissociation between classification and recognition observed by Squire and Knowlton (1995).

Second, there is now a wealth of evidence concerning the brain localization of conceptual knowledge. Brain imaging studies have suggested that knowledge is organized structurally at the neural level. In a pioneering study, Martin et al. (1996) explored the neural organization of conceptual knowledge by presenting participants with pictures of animals and tools to name while brain activity was recorded by positron emission tomography. As a control, participants saw nonsense objects. Compared to the control condition, brain activity for the meaningful objects was increased in the ventral temporal lobes bilaterally and in Broca's area in the left hemisphere. The latter is probably related to word generation. Relative to pictures of tools, pictures of animals produced increased activation in the left medial occipital lobe. Relative to pictures of animals, pictures of tools produced increased activation in the left dorsal temporal lobe and the left premotor region. This premotor area is also activated by imagined hand movements, suggesting that part of the conceptual representation of tools is a specification of the hand movements they afford. Overall, Martin et al.'s results – and many subsequent neuroimaging experiments – confirm that gross category distinctions are present in the way the brain organizes conceptual knowledge.

For a fuller review of recent psychological and neuroscience research on models of concept learning and representation, see Pothos and Wills (2011).

Concepts and Methods of Cognitive Therapies

Keith S Dobson and Liza Mastikhina, University of Calgary, Calgary, AB, Canada

Abstract

The cognitive therapies are one of a broad school of psychotherapies, which have evolved since they first emerged in the 1970s. This article discusses the three 'waves' of cognitive therapies, and provides definitions for many of the major forms of therapy. Issues of broad interest in the field, including mechanisms of action, and a recent move toward transdiagnostic approaches to therapy are also discussed. The article concludes with directions for future research and theory development.

Cognitive-behavioral therapies (CBTs) are a broad class of treatments that focus on cognitive and behavioral change. At their core, CBTs share three fundamental propositions (Dobson and Dobson, 2009). These propositions state that (1) it is possible to consciously monitor one's cognitive activity (i.e., 'the access hypothesis'), (2) cognitions impact emotions and subsequent behaviors (i.e., 'the meditational hypothesis'), and (3) one can intentionally modify the manner in which he/she responds to events in the environment (i.e., 'the change hypothesis'). Based on a large number of outcome trials, CBT has been suggested as the treatment of choice for a variety of psychological disorders (for a review, see Epp and Dobson, 2010). Further, the evidence base suggests that CBTs are in some instances as effective as pharmaceutical treatments, and that they are beneficial for certain medical problems such as chronic pain (cf Sensky, 2004). Given the breadth of the literature on the CBTs, this article will focus mainly on the basic concepts and will present the latest developments in the field.

'Classic' Cognitive Therapy

Cognitive therapy (CT) was developed in the latter part of the twentieth century and is associated for the most part with its originator, Dr Aaron Beck. CT was originally developed through Beck's work with depressed patients and is sometimes now referred to as 'classic' CT. While CT shares the core propositions of all CBTs, it differs to some extent from other CBTs in the organization of its theoretical underpinnings. The CT model proposes that emotional and behavioral responses are consequences of the manner in which an individual views, appraises, or perceives events around him/her (Beck, 1970). The content of the situation-specific appraisals differs based on the individual's activities and the appraisals can be accurate or distorted, as well as positive or negative. Thus, a principal goal in CT is to recognize and modify the patient's distorted appraisals of life events and make them more realistic and adaptive (Dobson and Dozois, 2009). Treatment is collaborative in nature and heavy emphasis is placed on educating the patient about the cognitive model. The 'collaborative empiricism' that is encouraged in CT involves the therapist designing learning experiences for the patients that can help them monitor their automatic thoughts; recognize how cognitions, affect, and behaviors influence each other; test the validity of their automatic thoughts and, if necessary, replace the distorted thoughts with more realistic and adaptive cognitions; and, finally, to identify and alter the underlying beliefs that make them susceptible to flawed patterns of thinking (Kendall and Bemis, 1983).

Cognitive therapists assume that experiences, and the meaning that patients attach to them, are idiosyncratic (Dobson and Dozois, 2009). Therefore, patients must take an active role in treatment and question the inferences that they make about their experiences. The therapist's role is to teach the patient the cognitive model and the underlying principles of CT, as well as to help the patient plan behavioral experiments that can serve as testing grounds for patients' hypotheses (i.e., thoughts and beliefs). Cognitive therapists do not lecture patients on a 'correct way to think,' nor do they assume the reasons why certain thoughts may cause distress. Rather, patients are treated as the experts of their own experiences, are asked to discuss their thoughts and mental images, and are taught how their appraisal of those mental events influences their emotional state. The CT therapist uses Socratic questioning, which is a technique that is characterized by the use of inductive questions, which encourage patients to think through different situations and come up with answers on their own.

Key Concepts

Cognitive Distortions and Automatic Thoughts

The concept of cognitive distortions was originally identified by Beck through his work with depressed patients. Cognitive distortions are errors that people sometimes make in their thinking (DeRubeis et al., 2009), which represent inaccurate assumptions that individuals make about themselves, the future, and the world. Some examples of cognitive distortions are all-or-nothing thinking (i.e., categorizing experiences as either good or bad), overgeneralizing (i.e., drawing global inferences from one occurrence), mind reading (i.e., making assumptions of what another person is thinking, despite having little evidence to support them), and making 'should' statements (i.e., thinking that one should or should not be doing something, rather than wishing to do it). CT teaches patients to attend to negative thoughts, to recognize when they make cognitive errors, and to correct these distortions based on evidence, where possible.

Automatic thoughts are surface-level thoughts that arise as part of our everyday experience and, therefore, can be readily identified (DeRubeis et al., 2009). In CT, patients are encouraged to recognize these thoughts, to evaluate them, and to explore the implications and meanings of habitual thoughts. Often, thoughts are viewed as hypotheses that need to be tested through behavioral experiments. For example, to test a thought such as 'nobody likes me at work,' a patient might have a conversation with his or her work colleagues and to observe their reactions to him or her, in order to determine whether the automatic thought receives support. It should be noted that automatic thoughts are not always negative in nature and that they can sometimes be positive and adaptive. If that is the case, and the patient is still experiencing emotional distress, the therapist would move on to identifying more ingrained concepts, such as beliefs and schemas, that can be potentially fueling the patient's negative state.

Core Beliefs, Assumptions, and Schemas

Cognitive schemas are fundamental cognitive structures, which serve to organize one's experience (DeRubeis et al., 2009). Schemas "represent the organized thought patterns that are acquired early in an individual's development" (Dobson and Dozois, 2009: p. 15), and that develop throughout the life span. Also referred to as 'core beliefs,' schemas are at the nucleus of the cognitive disturbance, and result in distorted perceptions, erroneous problem solving, and various psychological disorders (Dozois and Beck, 2008). Schemas can influence the type of activities that the individual chooses to engage in, which may, in turn, reinforce these core beliefs. When elicited by triggers, core beliefs often appear in an 'if–then' fashion (e.g., 'if I cannot be perfect, I am a failure'), which are also sometimes referred to as assumptions.

The 'deeper' level of work that is involved in CT involves work to identify and potentially change the patient's schemas or core beliefs (DeRubeis et al., 2009). Schemas are assessed through an in-depth analysis of the themes and patterns of thinking in the patient's negative experiences. Once the schemas are identified, their utility or validity is examined. Patients may be asked to list pros and cons of holding the core beliefs, as well as whether they have supporting evidence for them. This type of work helps patients to recognize the situations in which the schemas operate and what alternative inferences they might consider. Throughout treatment, the strength of the negative schemas is expected to diminish, as they become replaced with newer and more adaptive schemas.

Waves of CBTs

First Wave CBT

There have been three generations or 'waves' of therapies that can be ultimately referred to as CBTs (Hayes, 2004). Each wave has approached the patients' problems from a different angle, and therefore can be conceptualized as a different dimension of CT. The first wave began in the 1950s and was characterized by therapies of strictly behavioral nature that appeared as a reaction to the lack of empirical and theoretical support for the clinical paradigms of the day. Specifically, early behavior therapies were based on a set of basic principles that were established through scientific inquiry. In general, the behavioral therapies were founded on learning theory (e.g., conditioning) and conformed to well-established experimental paradigms. As these approaches grew, they were expanded to involve social learning models (Mischel, 1981), and what became called cognitive behavior modification (e.g., Meichenbaum, 1977). One of the goals of these approaches was to tackle problematic behaviors through cognitive assessment and modification.

Second Wave CBT

The second wave, referred to today as classic CT, integrated the central themes of the first wave behavior therapy, such as 'first-order change' (i.e., alteration of the form, frequency, and/or content of abnormal behavior; Hayes, 2004). Second wave CBT also addressed cognition from a direct and clinically relevant standpoint. It incorporated cognitive concepts and posited that irrational thoughts, maladaptive cognitive schemas, or faulty information-processing styles can be reduced or eliminated if they are detected, corrected, tested, and proven to be dysfunctional. Behavioral principles were still evident; however, cognitive concepts were emphasized to a much greater extent, and the main focus of the second wave was on information processing. Classic CBT is now a form of psychotherapy that is actively used around the world and has garnered a substantial amount of empirical support for its effectiveness in treating a variety of psychological disorders.

Although Beck's CT model viewed behavioral change as a means to test out the hypotheses regarding the patients' cognitions, it is not until the emergence of CBT in the late 1980s that behavioral strategies became fused with cognitive processes, with the goal of achieving behavioral and cognitive change. CBTs evolved and expanded over time, though, and can now be categorized into three classes, based on their relative focus on cognitive versus behavioral change: coping skills therapies, problem-solving therapies, and cognitive restructuring method (Dobson and Dozois, 2009).

Coping skills therapies focus on problems that are external to the patient (Dobson and Dozois, 2009), and aim to identify and alter the manner in which a patient might exacerbate the influence of negative events (e.g., by avoidance) and to teach him/her strategies to lessen the impact of those negative events (e.g., relaxation). The goal is to provide the patient with a repertoire of skills to promote coping in stressful situations. In contrast, cognitive restructuring therapies target more internal problems such as automatic thoughts, as well as long-term beliefs that lead to negative outcomes. An assumption of this type of therapy is that maladaptive thoughts result in emotional distress; therefore, the goal is to examine and challenge those maladaptive thought patterns and to establish more adaptive ones. Finally, the problem-solving type of CBT can be viewed as a combination of the coping skills and cognitive restructuring-focused approaches. Problem-solving therapies emphasize the patients' development and use of general strategies that can be used with a variety of personal

problems. These therapies also highlight the importance of an active collaboration in the therapeutic context.

Third Wave CBT

The third, and most recent, wave of CBT psychotherapies is distinguished by newer concepts, including metacognition, cognitive fusion, acceptance, mindfulness, dialectics, and spirituality (Hayes, 2004). Third wave therapies employ a variety of different techniques, but are similar to each other in that they emphasize the use of skills deficit models to examine the central maintaining mechanisms of various disorders (Hayes, 2004). Third wave psychotherapies include the following: acceptance and commitment treatment (ACT; Hayes, 2012), behavioral activation therapy (Martell et al., 2010), cognitive behavioral analysis system of psychotherapy (McCullough, 2000), dialectical behavioral therapy (DBT; Linehan and Koerner, 2012), metacognitive therapy (MCT; Wells, 2008), mindfulness-based cognitive therapy (MBCT; Segal et al., 2012), and schema therapy (Arntz and van Genderen, 2009).

Compared to first and second wave psychotherapies, the focus of third wave therapies is on the *function* of different cognitions and behaviors, rather than the content or accuracy of one's perception of his/her experience. Consequently, the emphasis is on 'second-order change,' which can be described as a fundamental shift in one's perception of reality. As with second wave CBTs, third wave therapies emphasize psychoeducation, and the patients' active practice with tools and techniques that they can apply to their everyday experience. Although third wave therapies are largely considered to be empirically supported (Kahl et al., 2012), currently there is not enough evidence to suggest that they are superior to classic CT. Below is a description of a number of third wave therapies.

ACT (Hayes, 2012) is based on the theory that the way individuals respond to mental events (e.g., thoughts) and experiences stems from the relationships they draw between them (Kahl et al., 2012). Thus, it is not the content of thoughts that is as critical in ACT, so much as the function that different types of thoughts serve. Treatment methods include psychoeducation about issues, such as nonjudgmental acceptance and embracement of one's present experience, exercises in mindfulness, and cognitive defusion (i.e., not taking one's emotional reaction as reflection of reality). Similar to CT, distancing from thoughts is considered to be a core skill, and negative thoughts are treated as beliefs rather than facts. During treatment, patients' values are elicited and discussed; however, unlike in CT, no restructuring techniques are employed, and behavioral homework assignments are not used as a means to restructure thoughts and to regulate mood, but to increase their psychological flexibility. Finally, heavy emphasis is placed on engagement in behavior that is driven by patients' values, instead of behavior that is driven by emotional and experiential avoidance. ACT has been shown to be an effective treatment for a variety of psychological disorders such as depression (Karlin et al., 2013) and mixed anxiety disorders (Arch et al., 2012).

MBCT (Segal et al., 2012) is closely related to ACT in its stance on the importance of embracing the present moment. It was originally developed as a relapse prevention therapy for depression. The key concepts employed in MBCT are psychoeducation about the nature of automatic thoughts, as well as how thoughts affect emotions and vice versa, and the practice of mindfulness and acceptance. The core goal is for patients to develop metacognitive awareness, but unlike in CT, the aim is not to change dysfunctional thoughts but to learn to monitor them, recognize them as thoughts and not facts, and distance oneself from them. There is substantial evidence for MBCT as maintenance therapy for preventing relapse in depression (cf Godfrin and van Heeringen, 2010) and some evidence for treatment of current symptoms of chronic depression (Barnhofer et al., 2009).

Another therapy that involves mindfulness is DBT (Linehan and Koerner, 2012). DBT was originally developed for parasuicidal patients who suffer from borderline personality disorder (BPD) and has been shown to be an effective treatment for it (e.g., McMain et al., 2009), but it has also been modified for a broader range of psychopathology such as substance use and eating disorders (Kahl et al., 2012). The core assumption of DBT is that skill deficits in the area of emotion regulation lie at the center of these disorders. As a result, DBT employs a broad "spectrum of skills in the areas of mindfulness, distress tolerance, emotion regulation, and interpersonal effectiveness" (Kahl et al., 2012: p. 524).

MCT (Wells, 2008) evolved directly from classical CT. It is based on the assumption that metacognitions (i.e., aspects of cognitions that control mental processes and the direction of thinking) need to change in order for psychological treatment to be effective. Unlike CT, there are no interventions that focus on the content of the patient's thinking (e.g., beliefs and their validity). Instead, MCT "uses attention training techniques to develop skills in cognitive flexibility, teaches a special form of mindfulness (detached mindfulness) and guides cognitive and behavioural experiments to change metacognition" (Kahl et al., 2012: p. 525). In other words, it focuses on the process of thinking, and presumes that the problem can be attributed to "inflexible and recurrent styles of thinking in response to negative thoughts, feelings, and beliefs" (Kahl et al., 2012: p. 525). Thus, one of the goals of MCT is the removal of those unhelpful styles of processing the information. It has been shown to be effective in treatment of generalized anxiety disorder (van der Heiden et al., 2012) and depression (Normann et al., 2014).

Similar to MCT, schema therapy (Arntz and van Genderen, 2009) is characterized by an emphasis on the concepts of schemas and modes. It was originally developed to treat personality disorders and other mental disorders of chronic nature (Kahl et al., 2012) and has been shown to be effective in the treatment of BPD (Farrell et al., 2009). The techniques in schema therapy are based on emotion activation methods of Gestalt and Psychodrama origin, but the patient is taught the models from a behavioral perspective. The therapist teaches cognitive techniques that can help the patient analyze and alter his/her dysfunctional beliefs about current, as well as past events.

A recent focus in CBT research has been on the deconstruction of cognitive therapies with a goal to find the active ingredients. One product of these component treatment studies has been behavioral activation therapy (Martell et al., 2010). It was found to be a stand-alone component with a "similar or superior efficacy compared with cognitive therapy" (Kahl et al., 2012: p. 523), especially in the context of

treatment of major depression (Dobson et al., 2008). The central aim in behavior activation is to supply the patient with stable and valued, yet diverse sources of positive reinforcement and meaning, in order to produce behavioral change (Martell et al., 2010). The key techniques include psychoeducation, activity monitoring, functional analysis of behavior, scheduling of nonavoidance activities, and trouble-shooting. It differs from classical CT in its emphasis on behavior change instead of cognitive change. Behavior activation is an active therapy and requires the therapist to take a problem-solving stance (Kahl et al., 2012).

Common Methods in Cognitive Therapies

As the technology related to the delivery of CBTs has grown, and new models and methods have been developed, the science related to the mechanisms of CBT has also grown. A considerable base of understanding about the necessary ingredients for successful CBT, as well as common factors in CBT has evolved, as described in the following sections.

Necessary Components of CBT

The CBTs are forms of psychotherapy, and as such contain aspects that are often seen in models of psychotherapy. For example, therapeutic alliance is an essential ingredient in all psychotherapies, including CBT (Beck and Dozois, 2011), and was shown to be modestly related to the total variance in therapy outcome (Horvath et al., 2011). CBT therapists, like other psychotherapists, require good interpersonal skills, such as warmth and unconditional positive regard, to facilitate their rapport with the patient (cf Castonguay et al., 2006). It is important for the patient to be comfortable with the therapist, to disclose his/her innermost thoughts and beliefs. Thus, building a good relationship is paramount; however, it is viewed as a necessary, but not sufficient condition for successful therapy outcome. The unique aspect of the therapeutic relationship that distinguishes CBT from other psychotherapies is the collaborative working alliance that is characterized by a mutual understanding of treatment goals.

Furthermore, the concept of collaborative empiricism in CBT involves the patient and therapist working together to attain treatment goals and to investigate the patient's thoughts and beliefs (Beck and Dozois, 2011). The rationale behind collaborative empiricism is that the client evaluates his/her intrinsic data (e.g., beliefs) based on empirical evidence and with the help of the therapist (cf Tee and Kazantzis, 2011). The two techniques that are most commonly employed are Socratic questioning/dialogue and guided discovery (cf Overholser, 2011). Based on the view that patients are experts on their own condition, guided discovery uses personally directed experiments to examine alternative thoughts and behaviors (Beck and Dozois, 2011), rather than simple persuasion by the therapist as to what course of action to take. The goal of the therapist is to instill a sense of curiosity in the patients and get them to think about their everyday experience. Socratic questioning is a form of guided discovery, which involves asking a series of inductive questions to assist the patient arrive at the answers on their own, based on existing evidence. In some cases, it may be possible that during this process the patient arrives at normative thoughts and convictions that oppose general evidence, but are nevertheless preferable to him/her. Depending on the issue at hand, the therapist can further attempt to help guide the patient toward appraisals that are adaptive and in line with existing evidence; however, in some cases, if unsuccessful, the intervention may need to be postponed until the patient is sufficiently ready to make the changes necessary to attain his/her treatment goals.

Psychoeducation is another important technique in CBT. Therapists educate patients about the therapeutic model and familiarize them with the key concepts and methods as they work with the patient throughout treatment. Psychoeducation equips patients with the knowledge of what skills are being taught, and how to broadly apply these skills, so that patients can use these skills during therapy and into the future, if the problem recurs.

Behavioral strategies are a common component of effective CBT. In second wave CBT, behavioral exercises are used to test the validity of patients' hypotheses (i.e., thoughts and beliefs), and to gather objective evidence on whether to accept, reject, or assimilate these ideas. The behavioral techniques also include exercises, such as exposure, to habituate the patient to feared stimuli, and relaxation, with the goal to encourage adaptive coping and cognitive change (Beck and Dozois, 2011). Behavioral exercises are also employed in third wave CBT, for example, to anchor patients in the present moment. For instance, the body scan exercise is used in MBCT, which invites patients to hold parts of their body in awareness, and to help them to become conscious of the physical sensations that are characteristic of the present moment.

Another central technique in CBT is thought monitoring. The patient is taught to become aware of his/her thoughts and to notice how they affect emotional outcomes and behavioral choices. In second wave CBT, the therapist may then help the patient to recognize maladaptive thoughts, and to restructure or eliminate those thoughts. In contrast, the focus in third wave CBT may be to become aware of those thoughts and to disengage from them. This idea is exemplified in the differences between the concepts of distancing and decentering, which are also techniques that are considered to be essential in CBT. Distancing, which is emphasized more in second wave therapies, involves recognizing thoughts as beliefs and internal events rather than facts. On the other hand, decentering is more typical in third wave CBT, and involves viewing thoughts as beliefs, recognizing their impermanent nature, and learning to let go of them.

The assignment of homework is a component that is present in all CBTs and is integral to therapeutic success. Patients need to take an active role in their recovery, and the completion of homework assignments increases the sense of mastery about new skills, and provides increased control over interpersonal, environmental, and other conditions (Beck and Dozois, 2011). Homework also allows patients to practice the newly learned skills in the 'real world,' which aids with the generalizability of the skills. Finally, successful homework provides accomplishments, which can solidify the concepts that patients learned in session. For example, a patient who is afraid of public speaking, but who learns that the feeling of discomfort that is experienced when giving a presentation at work eventually decreases with

practice, is likely to be encouraged to try to continue giving other public presentations.

Barlow's Unified Protocol

As noted above, research has examined the utility of certain components of CBT and their utility for a range of psychological disorders. More recently, Barlow et al. (2010) have described a 'unified protocol,' which they proposed is a set of principles based on cognitive behavioral theory that can be used to treat many emotional disorders. Unlike the applications of CBT to specific disorders, the unified protocol does not target specific symptoms, but rather emphasizes the underlying mechanisms that exist along the full spectrum of disorders. The unified protocol presumes that individuals with emotional disorders use a set of maladaptive strategies to regulate their emotions, which are used to either avoid or diminish their unpleasant emotions, but that these strategies are counterproductive in that they perpetuate the very emotions they used to avoid. The goal of unified protocol is not to eliminate negative emotions, but, instead, to get patients to learn to tolerate them at a more functional level and learn that negative emotions can have adaptive functions. The protocol is essentially a skills building model, which can be conducted in much the same fashion as other forms of CBT.

The unified protocol lists five core skills that are combined into three modules that are introduced sequentially, albeit with flexibility, depending on the patients' individual needs and understanding of the treatment approach. The first core skill is called present-focused emotion awareness and presents patients with a model that emphasizes the interaction among thoughts, feelings, and behaviors. The assumption is that this model of emotion provides patients a more objective understanding of their emotional experience, which, in turn, fosters their emotional awareness. Emotional awareness is viewed as a necessary skill for understanding of the treatment concepts that are subsequently introduced.

The second core skill in the unified protocol is cognitive flexibility, which involves the challenge of the patients' negative evaluations of external and internal events (e.g., physical sensations and emotions) and an increase in cognitive flexibility. Adapted from Beck's concepts of cognitive distortions, a focus is placed on probability overestimation and catastrophizing. Specifically, patients are instructed to think about how likely the negative event is to occur and how negative can the consequences of that event be if it did occur.

Recognition of emotion avoidance and emotion-driven behaviors is the third core skill in the unified protocol. This skill involves identification and modification of maladaptive patterns of behaviors driven primarily by emotions (Barlow et al., 2010). The therapist teaches patients to identify patterns of their maladaptive thinking and change them, in order to regulate their emotions. Relatedly, the fourth core skill is awareness and tolerance of physical sensations, which is attainted through interoceptive exposure practices. The goal is to, again, bring patients' awareness to the physical experiences of emotion and to teach them the reciprocal nature of the relationships among sensations, thoughts, and feelings. Finally, the fifth core skill involves 'exposure exercises.' The goal of exposure exercises is to elicit emotional experiences by exposing patients to situations that evoke the emotion of interest (e.g., anxious emotions in social situations for someone with social anxiety). The emotional experience exercises typically range from least intense to most intense. Patients are encouraged to fully experience each situation, so that the therapist can identify potential avoidance or safety behaviors. The therapist and patient also work on reduction of safety behaviors and the acquisition of new learning experiences that do not result in negative emotions.

The 'unified protocol' is still an emergent concept in the CBT literature; therefore, more research is needed to determine its effectiveness in treatment of emotional disorders. However, there is preliminary evidence to suggest that it is efficacious in treatment of depression and anxiety disorders (Farchione et al., 2012; de Ornelas et al., 2013). Finally, it should be noted that other experts in the field of psychotherapy have suggested core skills that improve the efficacy and effectiveness of psychotherapy that are different from those listed in Barlow and colleagues' 'unified protocol' (cf Grawe, 2004); however, they are not discussed here because of their differing theoretical basis.

Future Research Directions

Despite the large amount of extant research on CBT therapies and mechanisms, and the existence of several journals that disseminate this work, several aspects of CBT require more research. Several of the key issues that currently exist include the relative effectiveness of the third wave therapies, long-term effects of CBT, optimizing delivery of CBT, understanding the mechanisms of change, and developing a better understanding of its suitability for, or limitations with various psychological problems.

First, there is a need for more research that compares the effectiveness of third wave therapies to classic CT, so as to determine whether or not they result in superior outcomes (Kahl et al., 2012). As well, more data are needed with respect to their suitability for certain psychological disorders and their limitations. Researchers have urged more meditational analyses of the effects of third wave therapies, specifically in relation to different emotion regulation strategies and whether they have an additional benefit to standard CBT. Third wave CBT also opens the possibility of tailored emotion regulation strategies, which might be selectively used with those patients who are most likely to benefit (Hoffman et al., 2010).

There is a need for more data regarding the most effective use of cognitive therapies. Research needs to examine the extent to which therapists are able to learn cognitive therapies and to follow treatment protocols with their patients in various contexts and regular clinical practice (DeRubeis et al., 2009). There is a further need for research on the mechanisms of change in cognitive therapies that result in the most stable benefits (Beck and Dozois, 2011). Particularly, there is a need for a better understanding of the interplay among "cognitive, affective, motivational, and behavioural" (Beck and Dozois, 2011: p. 406) factors in cognitive therapies. One limitation of process research is that it tends to be correlational in nature. Experimental studies are needed to supplement correlational research and to document the processes that lead to a positive therapeutic outcome (DeRubeis et al., 2009).

Continued research regarding the applicability of CBT to various disorders, as well as the long-term outcomes of treatment is needed. While research has primarily focused on relapse prevention in the months after the termination of treatment, studies need to be conducted to include even longer follow-up assessments, to provide estimates of both medium effects and long-term effects of cognitive therapies (DeRubeis et al., 2009). Comparative long-term analyses, including cost–benefit analyses with other modes of therapy, would also provide important information from the perspective of health-care policy and funding.

Conceptual History: *Begriffsgeschichte*

Mario Wimmer, University of California Berkeley, Berkeley, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Conceptual history is a mode of historical inquiry concerned with the problem of the change in the semantics of particular concepts. The article outlines its historical formation in both the disciplines of history (R. Koebner, O. Brunner, C. Schmitt, R. Koselleck) and of philosophy (R. Eucken, R. Eisler, E. Rothacker), its further institutional and intellectual development, as well as an overview of the major methodological issues. This article also puts conceptual history in the context of other fields with similar methodological concerns such as the history of ideas and mentalities, intellectual history, historical epistemology as well as Luhmann's sociology.

Conceptual history is a field of historical study concerned with the problem of the change in the semantics of particular concepts. It engages with a general problem in the writing of history: the difference between the language of the sources and the analytical categories of the historian, more specifically the change in semantics over time, as every historical-empirical approach has to deal with the problem of the changing semantics of historical sources, be they texts or other artifacts from the past.

This problem has a long history in historiography. Conceptual history is one specific epistemological formation in this long history of a more general problem, the study of the historicity of the conditions of the emergence of meaning and sense, experience and perspective. Ever since the formation of the historical disciplines in the late eighteenth century the criticohistorical reading of written documents has been one of their basic tools and tasks. These issues have been the subject of international debates e.g., as language and written matter as the necessary condition of historical thought (a widely discussed issue in historical methodology in classical textbooks from Johann G. Droysen to Charles Langlois/Charles-Victor Seignobos), the problem of symbolic (Ernst Cassirer) or intellectual (Johan Huizinga) forms, or under the label of the *linguistic turn* (Richard Rorty). Since the 1960s this universal challenge of historical thinking was reconsidered as the study of discourses and their various institutional structures and material conditions that contribute to the emergence of historical formations (epistemes) of cultural production (Michel Foucault), or more recent debates in labor history on how the experience of class consciousness is structured by language (Jones, 1983; Scott, 1974; Rancière, 1989).

Ever since conventional representation has become problematic at the beginning of the twentieth century, with a transformation for example witnessed by the fictional "Letter of Lord Chandos" (Hofmannsthal, 2005) and, anticipated by Friedrich Nietzsche, this crisis of language became thematic in such different contexts as philosophy of language, pragmatism, Gottlob Frege's logic, Edmund Husserl's phenomenology, Ferdinand de Saussure's linguistic, or Freudian psychoanalysis. In other words: the situation between history and its language had significantly changed and generated fresh scholarship on the problem. In the German context it has been conceptual history or history of concepts (*Begriffsgeschichte*) that dealt with the phenomenological problem of historical sources and their language in a particular way: Scholars deemed past events or a set of historical conditions that are incorporated as condensed experience in concepts or notions. The language of the sources contributes to their formation; thus, we need to engage with the historicity of the concepts of analysis with respect to the language of historical sources. As a consequence conceptual history studies the changing semantics of concepts or notions over time. Indeed, it is not self-evident that concepts *do*, or at least *can*, have a history. It is only if we acknowledge the event-character of discursive practices that concepts themselves can be read in historical context.

While *Begriffsgeschichte* is still a well established field in the history of philosophy and philosophical terminology, nowadays most historians along with political and social scientists, linguists or cultural theorists prefer an approach that allows for a broader engagement with semantic constellations and discursive practices. This is not the only sense in which the history of concepts is not a strictly formal discipline but a set of methodological tools that can follow different – historical, philosophical, or cultural – paths. Since the 1980s there has been a gradual shift from the study of individual concepts toward a more general interest in the systematic study of language, or as Willibald Steinmetz (born 1957) recently put it, semantic 'situations' as a basis for historical-social, cultural, and conceptual understanding. Conceptual history and, the larger field of so-called historical semantics, enjoyed their most formative phase in parallel with the development of historical metaphorology, i.e., the study of the change of metaphors over time – though, the latter is often ostracized. (Bödeker, 2002) All these approaches share specific goals and certain characteristics with the history of ideas, discourse analysis, the history and philosophy of science, as well as–in different ways – lexicology and the linguistic study of semantic change.

Initially, conceptual history was mostly considered a 'German' approach, which is commonly traced back to two monumental projects, the *Historisches Wörterbuch der Philosophie* (Dictionary of Philosophical Terminology) and the lexicon *Geschichtliche Grundbegriffe* (thereafter *Grundbegriffe*, Basic Concepts in History: An Historical Dictionary of Political and Social Language in Germany), as well as the work of the historian Reinhart Koselleck (1923–2006), one of the most influential German historians in the twentieth century and an

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03074-9

original theorist of history. The project of the *Grundbegriffe* was derived from comparative studies of the semantic changes in 122 basic sociopolitical concepts in different European languages (with a focus on German) around 1800, in some cases reaching back to antiquity. The understanding of basic concepts (*Grundbegriffe*) for the encyclopedic project of the *Grundbegriffe* was distinguished not only by its exclusion of concepts that define or categorize (*Leitbegriffe*), keywords (*Schlüsselwörter*), catchphrases or slogans (*Schlagwörter*) (for the history of buzz-words see Bauer, 1920; Bahner, 1963), but also by the attempt to at least try to consider multilinguism and thus reference texts not only in German (Old, Middle, and modern), but also classical and medieval Latin, classical Greek, French, English, and Italian.

Only a few publications in English provide a good starting point and introduction to the field: Melvin Richter's *The History of Political and Social Concepts* (1995); the more focused books by Niels Akerstrom Andersen (2003) and Niklas Olsen (2012); several introductions to the oeuvre of Koselleck give broad contextualizations (see also the 1989 special issue of *History Workshop Journal* on 'Language and History,' in particular Schöttler, 1989).

Conceptual History before and after Koselleck

To my knowledge, the use of the word *Begriffsgeschichte* goes back to G.W.F. Hegel's lectures on the Philosophy of History where he introduced it as a variation on 'reflexive history,' as a form of cultural and intellectual history that defines its objects close to philosophy. This rather particular understanding of the history of concepts has not prevailed. The German tradition of *Begriffsgeschichte* has instead other origins in the fields of philosophy and history. Rudolf Eucken's (1846–1926) *History and Critique of Basic Concept of the Present Day* (1878) along with his *History of Philosophical Terminology* (1879) were among the first publications in the history of concepts published in German language, though different from our current understanding in terms of its conception and approach. Another early example in the study of the historical formation of philosophical concepts was Rudolf Eisler's (1873–1926) single-authored *Dictionary of Philosophical Terminology and Notions* first published in 1899. Eisler was an Austrian philosopher, who remained a private scholar without a university career due to antisemitic prejudices in German-speaking academia. Yet, although between 1943 and 1948 four new philosophical dictionaries would appear in German, none with success, and until the first issue of the new periodical *Archiv für Begriffsgeschichte* (Archive for Conceptual History, edited by the German philosopher Erich Rothacker, 1888–1965) was published in 1955, the revised edition of Eisler's multivolume *Wörterbuch* remained the standard reference for academic philosophy besides the fact that it was not systematic in its philological approach to the history of philosophical terminology.

Rothacker's *Archiv* for its part was meant to be a collection of studies in the historical semantics of mostly philosophical concepts as a resource for a future encyclopedia of conceptual history. Indeed, its contributors were – and still are – mostly philosophers and intellectual historians. For decades it served as a platform for vivid discussions and intellectual exchange in both the fields of conceptual history and historical metaphorology. Most contributions gave crisp, sometimes comparably narrow historical overviews on certain concepts occasionally grouped around thematic issues, but it also allowed for long, almost monographic articles on important topics, among them the remarkable book-length essay by Hans Blumenberg, *Paradigms for a Metaphorology*. This essay not only earned him a university position but became an instant classic and was later published as a book in its own right (Blumenberg, 2010 (German 1960)).

It was only in 1972 when Joachim Ritter (1903–74), Karlfried Gründer (1928–2011), and Gottfried Gabriel (born 1943) initiated the multivolume Dictionary of Philosophical Terminology when Rothacker's vision of a complete historical survey of philosophical concepts began to become reality. Nonetheless the editors began to present their own project as a complete reedition of Eisler's *Wörterbuch*, even though the many volumes of the *Archiv* had done much of the spadework. By the time that the last volume of the *Wörterbuch* was published in 1997 it had become one of the most important enterprises of German *Geisteswissenschaften* after World War II; it contains about 6000 entries on 3670 philosophical concepts by more than 1500 authors. What distinguishes their various contributions is that they do not aim at fixed and dogmatic definitions of philosophical concepts, but every article discusses the origin, evolution, and transformation of the meaning of a concept or notion through systematic reference to source texts.

In the discipline of history, as opposed to philosophy, the situation was similar only in one respect: Again, conceptual history was pioneered by a German-Jewish scholar, Richard Koebner (1885–1958), whose work was again marginalized by his German colleagues even though his approach also followed, at least to some degree, in their then dominant German 'Research of the East' (*Ostforschung*), which since the 1920s contributed to the planning of ethnic cleansing of local indigenous populations and settlement of Germans aiming at "Germanizing" Central and Eastern Europe (Michael Burleigh, 1988). Koebner's work in the field started with his Berlin dissertation on the concept of marriage in late medieval Germany (Koebner, 1911). His Habilitation on the history of Cologne in 1919 involved discussions of several methodological problems in conceptual history; it was followed by a series of articles on various concepts. In 1934, after he was forced out of Nazi Germany and accepted a position at the Hebrew University in Jerusalem, he published his last article in German, a groundbreaking study on conceptual problems in cultural history. However his seminal article 'Semantics and Historiography' (1953) together with other important contributions to the field of conceptual history (on the history of the concepts of Western Civilization, Empire, or Imperialism) should have inspired those German historians, who during and following World War II established the seemingly new field of *Begriffsgeschichte*. Instead, they often referred to older studies in German literature and linguistics – as demonstrated in detail by Jan-Marco Sawilla (2004) – thus Koebner and his work were and mostly remain ignored – except for the homage paid him by Koselleck on the occasion of a talk on the history of concepts he delivered in Israel (Koselleck, 2006; the article was recently

also published in German translation in Joas and Vogt, 2011). Similar claims could be made for other exiled German scholars such as Paul Oskar Kristeller, Ernst Cassirer, or Karl Mannheim.

Concepts in the History of Ideas

Early conceptual history had also structural similarities with new disciplines emerging in the early twentieth century, such as the history of ideas and mentalities. In Germany it was most prominently the work of Friedrich Meinecke that was driven by a similar interest in the change of political ideas over time (e.g., Meinecke, 1924). The work of the American philosopher and intellectual historian Arthur O. Lovejoy (1873–1962) in the history of ideas shares various similarities with the study of the history of concepts. His attempt to identify what he called 'unit-ideas,' or individual concepts, as well as the study of their change over time suggests an approach rather concerned with intellectual and cultural than social and political history; precisely because of the reduction of his argumentation to ideas or concepts as basic 'units' of historical study. In his famous *The Great Chain of Being* (1933) he outlined and pursued an approach that in many respects shared interests with research in the history of concepts and German History of Ideas.

The so-called Cambridge School (Quentin Skinner, J.G.A. Pocock, among others) in intellectual history followed in some respects the model set by Lovejoy's history of ideas. However, there were few affinities with German *Begriffsgeschichte*. Indeed, Pocock admitted to not even being aware of the German studies in the history of political language until he was invited to contribute to a workshop on the occasion of the completion of the *Grundbegriffe*. (Lehmann and Richter, 1996) Nonetheless, different attempts have been made to find common ground between these different approaches, even though the main bone of contention always was – and still remains – the relation between the 'internal' logic of political language of the past and its 'external' reference to history proper (what Koselleck liked to call '*Sachgeschichte*'); in other words: a focus on intellectual and political language on the on side of the channel, and the attempt to relate semantic change to social and political history. While the Cambridge method was based on language philosophy (Ludwig Wittgenstein (1889–1951), John L. Austin (1911–60) among others) and exclusively focused on the analysis of political language and its relation to political theory, the German approach engaged emphatically with the dynamic between the history of concepts and their relation to experience of the historical past and not only in that respect to social history at large. (For a comparative approach of Anglo-Saxon and German conceptual history see Palonen, 2004; Leonhard, 2004.)

The French Approach: the History of Mentalities and Philosophy of Science

In France at the turn from nineteenth to twentieth century an interdisciplinary group of scholars formed around the philosopher Henri Berr (1863–1954). The group's intellectual gravity shifted toward historical study and Berr's ideal of synthesis. This collaborative spirit contributed to the founding of the journal *Annales* (in 1929) by the eminent historians Marc Bloch (1886–1944) and Lucien Febvre (1876–1956). They involved themselves in the historical study of mentalities, thus also paying attention to relation between language and history (see also the considerations of Barthes, 1981). In a rubric of the new journal Febvre published a series of articles (e.g., on 'frontier,' 'civilization,' or 'work') under a separate section entitled '*Les mots et les choses*' (*Words and Things*). Bloch and Febvre were both engrossed by historical-comparative linguistics as well as Saussurian structural linguistics. Their colleague Berr also edited a volume on the history of the concept of *civilization* with contributions by Febvre, Marcel Mauss, and Emile Tonnelat, among others. The volume was a signal of a different method of writing the history of a concept as it aimed at transnational comparisons and was critical of the idea of progress. Although it belonged to the tradition of the Enlightenment encyclopedia, even the *Encyclopédie française*, edited by Febvre and Anatole de Monzie, can be viewed as an early project in the history of concepts insofar as it followed a radical humanist, theoretical, and, only to some extent, historical conception of a total synthesis of diverse elements that allowed for a comprehensive thinking of our world (Schöttler, 2005).

Surprisingly, one can find hardly any connection between German conceptual history and the major studies in the history of scientific concepts in French and American History and Philosophy of Science. Discourse analysis and the work of Michel Foucault (1926–84) may be considered one of the few exceptions in this respect, even so the work of the French-American tradition of historical epistemology continued to be as ill-informed of the project of *Begriffsgeschichte* as German and other international scholars in this field are of the works of Georges Canguilhem (1904–95) or Ian Hacking (born 1936). Ever since the introduction of an 'historical apriori,' i.e., the historicity of the conditions of possibility of perception, by Edmund Husserl (1859–1938) to the philosophy of science, French, and later North American, historians and philosophers of science have become concerned with the history of scientific concepts. Thus, Gaston Bachelard (1884–1962) argued convincingly that knowledge could only be adequately understood if studied empirically through its constituent concepts in their historical context and development. The earliest examples of studies in the history of scientific concepts are Canguilhem's books on the emergence and development of the concepts of *reflex* (Canguilhem, 1955) and of *evolution* (Canguilhem, 1952). Both books make compelling cases for a new way of writing the history of science as a history of scientific concepts rather than a history of theories that employ those concepts. It was Foucault who steered this approach toward an analysis of institutionalized modes of speaking, its rules, and arrangement as well as the historical conditions for the possibility of statements; he was less interested in individual concepts so much as what he termed discursive practices and formations. The Canadian historian and sociologist Régine Robin (born 1939) in turn adopted this approach for the quantitative study of historical semantics, including microanalyses of individual concepts. The Canadian-French analytical philosopher Hacking engaged in this tradition when he published his study on *The Emergence of Probability* (1975). Ever since then Hacking has

made important contributions not only to the methodology but also to the actual history of scientific concepts inspiring studies by Lorraine Daston (born 1951), Peter Galison (born 1955), and others on concepts like *objectivity*, *probability*, or *empiricism*.

The Lexicon Geschichtliche Grundbegriffe

Returning to the eminent historian of conceptual history, Reinhart Koselleck, let us remember that although he considered himself an academic outsider, he would become not only the executive editor of one of the big collaborative projects in twentieth-century humanities, but also one of the leading scholars in the history of concepts; and certainly the strongest voice in attempting to develop a theoretical and methodological basis for *Begriffsgeschichte* in the larger context of a social history of politics and the public sphere. In Koselleck's understanding, *Begriffsgeschichte* was not only "concerned with political or social events and circumstances" (Koselleck, 1985(German 1979): p. 85) articulated in the language of their respective historical sources, but the basic concepts also indicated the "process of transformation into modernity"; only this nexus of approaches would allow a deeper understanding and reflexive use of our language today. In that sense, evolving concepts would embody novel experiences and relate to shifts and ruptures in semantics. The transformation of basic concepts of around 1800 (the so-called '*Sattelzeit*,' which translates to English as 'saddle-time' or threshold) introduced a temporal dimension to the formation of meaning; according to Koselleck they are 'Janus-faced': they capture both past and future perspectives of this period of transformation. Koselleck assumed that around 1800 key concepts changed and new concepts emerged, which embodied historical time, for example 'development,' 'revolution,' or the famous 'history as such' (history in the collective singular), and that this change in semantics would parallel a new understanding of European modernity.

This close connection between the language of the sources and our present understanding of past events was predominantly informed by the work of both the Austrian medievalist Otto Brunner (1898–1982) as well as by the political theorist Carl Schmitt (1888–1985). Brunner's book *Land and Lordship*, originally published as a study in German *Volksgeschichte*, was concerned with the language of sources in opposition to an approach that employs concepts from legal and constitutional theory in order to write the history of the State. Brunner's work became seminal for the methodology of German conceptual history and – in a reedited version that replaced the ideological Nazi terminology like race, people, etc. by 'neutral' notions like 'structure' (Gadi Algazi, 1997) – is to date considered a classic in medieval studies. Koselleck emphasized that without the work of Brunner the lexicon "would have been unthinkable," (Koselleck, 1972) Schmitt for his part had been Koselleck's mentor during his dissertation work on *Critique and Crisis* at Heidelberg; it was Schmitt, who suggested focusing on the changing of the two title concepts alongside others like 'war,' 'civil war,' and 'revolution.' The historical study of the change of meaning of concepts aided by crisp historical arguments and original theoretical points became distinctive features of his *oeuvre*. *Critique and Crisis* was received as a contribution to both history and sociopolitical theory, but criticized for its politically conservative attitude (most prominently by Habermas, 1977). Although often not considered part of a school, Koselleck and his early work was perceived as being part of a politically conservative group of German historians. (cf Olsen, 2012)

With his habilitation *Prussia between Reform and Revolution* (1965) Koselleck's work became reasonably independent from the early political and methodological circumstances mentioned above. He finally committed to the historical discipline. From now on he insisted on the necessity of theory for the historical discipline by coining a whole set of methodological concepts, which were based on his research in historical semantics and translate a set of philosophical ideas from the phenomenological tradition (like *horizon*, *life world*, or *historicity*) into methodological tools for historians, such as *Erfahrungsraum* (space of experience) and *Erwartungshorizont* (space of expectation), *Sattelzeit*, among many others; all of which became cornerstones of his methodology of conceptual history (Schinkel, 2005). However, the practice of conceptual history certainly departed to some extent from Koselleck's presumptions and guidelines, in some cases to the extent that sections or whole articles were rejected by the editors because of their methodological dissents (cf introduction to the *Grundbegriffe*).

From 1972 onward, Koselleck coedited, together with the historians Werner Conze (1910–86) and Otto Brunner (1898–1982), the eight-volume encyclopedia dedicating most of his research and intellectual engagement to this project. In accordance to the imperative that history is to be rewritten, Koselleck instead revised and adopted not only the methodological framework of the *Grundbegriffe* but started to rethink conceptual history from within the more general context of historical semantics and the need for theory in the historical discipline. Consequently, in his later work he returned to a concern that was already present in his early writings (Olsen, 2012): the dialectic between his reflections on historical semantics and an anthropological theory of history that reframes conceptual history (Hoffmann, 2010).

Critique, Transformation, and Resumption of the Encyclopedia of Basic Concepts in History

The project of the *Grundbegriffe* and Koselleck's early work in the history of concepts were both highly acclaimed and the subjects of severe critique. Probably the strongest criticism came from Koselleck's colleague at Bielefeld, the social historian Hans-Ulrich Wehler (born 1931), who, like others, claimed that not only did conceptual history not contribute to the urgent questions of the historical discipline but also that it was an intellectual dead-end and would have no impact. His colleague at Stanford, James Sheehan (born 1937), joined him in the critique of the *Grundbegriffe* (Sheehan, 1978) but mostly of its conception and methodology. For Sheehan, the corpus of sources was insufficiently representative and not diverse enough to plumb the depths of popular culture and everyday life (Lüdtke, 1995).

Besides all efforts to the contrary, the focus and perspective of the *Grundbegriffe* remained on German history. It was also

criticized for its attention to the origins and evolution of a concept rather than situational semantics and diachronic differences, as well as narrow range of reference in canonical texts, authors, and published sources. The attempt to include newspaper articles, journals, pamphlets and records was not particularly successful despite many extensive citations, which should document the language of the sources and give voice to their 'right of veto' (Koselleck). Substantial critique and enhancement came mostly from inside the field (e.g., Kittsteiner, 1991; Steinmetz, 1993; Busse et al., 1994; Lüsebrink and Reichardt, 1997; Palonen, 1997; Reichardt, 1998), yet, even by Koselleck himself, who kept revising the theoretical framework of conceptual history.

However, any critique should repay its subject in the same coin, and at least two major critical responses almost outweighed the *Grundbegriffe* in their ambition and conception: the *Handbuch politisch-sozialer Grundbegriffe in Frankreich: 1680–1820* (Companion to Political-Social Basic Concepts in France), directed by Rolf Reichardt (born 1940) and published in 20 volumes; and the *Aesthetic Basic Concepts. Historical Dictionary in Seven Volumes*, conceptualized under the institutional umbrella of the East German Academy of Sciences, and edited by the literary scholar Karlheinz Barck (1934–2012), *Martin Fontius* (*born 1934*), *Friedrich Wolfzettel* (*born 1941*), and *Burkhart Steinwachs* at the Berlin think-tank *Zentrum für Literaturforschung* (*ZfL*), finally released in 1992–2005. Currently, the ZfL continues research in the field with an emphasis on both interdisciplinary research and conceptual history of the sciences (Müller and Schmieder, 2008).

In contrast to the *Grundbegriffe*, the *Companion* had strong preference for diachronic differences, included a much broader variety of sources, and thus offered a survey of the most significant social and political concepts in France from the beginning of the Enlightenment to the Restoration. Its interest lay largely in the literary, social, and political conception of reality. The long introduction spells out the methodological rigor with which the whole enterprise was undertaken: it focused on the changes in language and meaning before, during, and after the French Revolution by using a methodological mix of the quantitative techniques of lexicometry together with the analysis of historical semantic of concepts including a standardized set of sources ranging from literary texts, newspapers, journals, tracts, and pamphlets to folk songs, popular images, and other products of mass print culture, all in order to pay attention to the social history of the illiterate majority. The handbook of aesthetic concepts, on the other hand, programmatically allowed its authors an expansive methodological and conceptual freedom. It aimed at balancing the history of aesthetic thought through the history of its somewhat 170 major concepts. Yet, it was by no means comparable in its theoretical ambition, and thus did not attempt in establishing an independent method – neither applicable for the project nor for conceptual history at large.

The problem of semantics was also addressed in social theory, mostly as part of a theory of modernity that sustained the assumption of a major transformation around 1800. Koselleck's colleague at Bielefeld, the German sociologist Niklas Luhmann (1927–98), introduced the concept of semantics to his social theory of communication in order to deal with the production of meaning or sensemaking within social systems (Luhmann, 1995). Meaning for him is the selective realization of possibilities within a given social system; semantics in that sense are structures within a concrete system that allow for the preservation of certain premises of the production of meaning. According to Luhmann, semantics evolve in retrospective adaptation to the autopoietic evolution of social structures (Stäheli, 1997).

International Trends in Conceptual History

Today, the practice of conceptual history belongs to a broader understanding of historical semantics as well as to political and intellectual history. It has become an international endeavor absorbing many different national traditions, most prominently those of Finland, the Netherlands, and the Spanish-speaking world, with the respective flagship-projects often modeled after the *Grundbegriffe*. Bibliographies for the growing scholarship are available at http://www.hpscg.org/bibliography (last updated 2008) and http://www.historyofconcepts.org/database (currently updated). Curiously, Russian conceptual history mostly remains the domain of German-speaking scholars. (Thiergen, 2006; Sperling, 2012) Recently, the import of German historical scholarship to China also includes historical semantics. (e.g., Wan-ting, 2012) All these national traditions of conceptual history aspire to international comparison but are mostly busy with the groundwork in their respective national contexts. On a methodological level historians like Willibald Steinmetz (born 1957) advocate a nonnominalistic approach that deals not only with concepts but the historical semantics of different kinds of condensed past experiences (including popular and visual culture as well as unpublished source materials) in a transnational context. Along these lines not only counterconcepts (Junge and Postoutenko, 2011) but also blind spots and eclipses can play a significant role. (Hölscher, 2009). Similar claims have been made for the necessity for a historical semantics that pays attention to performative and discursive practices, as well as for the historical-semantic inquiry into the imaginary (e.g., Koselleck, 1985; Wimmer, 2012) and the visual (Kohle and Reichardt, 2008).

For research in the historical semantics in the premodern era the situation is slightly different. As the concept-oriented approach reaches its limits for research in this period, the analysis of historical semantics is the most profitable route forward. The existing canonical corpora of medieval sources that have been edited since the nineteenth century (and which were digitized early on) have become the resource of quantitative scrutiny in the historical semantics of premodern Europe. This applies mostly to Latin medieval discourse; a similar scrutiny of vernacular languages remains a desideratum (Jussen et al., 2008). Whatever the case, the problem of multilingual communication in premodern times, necessarily suggests different research strategies.

In recent periods, new and easily accessible technologies like Google book search and the experimental Ngram toolbox (Schmidt, 2012) have become available, which allow for large-scale literary computing that triggered a revival of quantitative approaches to historical semantics. Digital

humanists like Franco Moretti (2013) have argued for a new form of macroanalysis (Jockers, 2013) of so-called big data in the humanities, which as the huge collaborative editorial projects of the nineteenth century have a tradition of dealing with large corpora of texts (Bloch, 1994) but have developed few methodological procedures for dealing with them. At this point it seems unclear whether the new technological possibilities will allow for hermeneutic innovation that can replace or revolutionize critical and close reading or will only change the ways we access, select, and connect texts. However, the data deluge will not put an end to the necessity for theory but will ultimately urge us to rethink the data (as well as the algorithms that process and read these digital materials) theoretically and historically.

Besides the *Archiv* mentioned above to date, several journals have appeared concerned with research into historical semantics and the history of concepts, i.e., the US *Journal for the History of Ideas* (since 1940); the French *Cahier de Lexicologie* (since 1959); Italian *Journal of Interdisciplinary History of Ide*as (since 2012); the German *Forum Interdisziplinäre Begriffsgeschichte* (since 2012); the Finnish periodical *Rediscriptions. Yearbook of Political Thought and Conceptual History* (since 1997); the international journal *Contributions to the History of Concepts* (since 2005); and the *Journal of the History of Ideas in East Asia* (since 2011). In particular the latter pair provides platforms for an international community to publish original empirical and theoretical research.

Today conceptual history is mostly understood and practiced within a broader constituency of the study of semantic change, to some extent taking issue with the methodology of discourse analysis. One of the major concerns seems to transgress national traditions and languages in order to provide transnational and transcultural analyses of semantic change (for the international debate see Hampsher-Monk et al., 1998; for Finland see Ahonen, 2006; for Italy Chignola, 2002), including regions that have so far not been subject of study, such as Russia (Sperling, 2012) and former colonies like India (Pernau, 2012). Future approaches might include the study of traveling concepts (Przyrembel, 2011) or even blind spots (Hölscher, 2009), which allow for transcultural comparison without perpetuating reigning models of power and meaning. Another trend will probably be a conceptual history of the last century, as there exists relatively little research on the history of concepts in the twentieth century.

Finally, the research experience in the field may open even more perspectives on social and cultural history and the history of everyday life as well as historical metaphorology and discourse analysis with the common goal of maintaining an as wide horizon as possible for fruitful future research in the field. The aim of conceptual history should, maybe paradoxically, become to do without a *telos*, in order to engage in new ways with contingency, singularity, and the very meaning of the event as to keep the writing of history open for a history that goes beyond the limits of rationality.

Conditional Cash Transfers: Influence on Marriage and Fertility

Sarah Baird, Milken Institute School of Public Health, George Washington University, Washington, DC, USA

Abstract

This article discusses the theoretical foundations and investigates the existing evidence on the impact of conditional cash transfers (CCTs) on the marriage and fertility of the transfer recipient (typically the adult female in the household) as well as the school-age beneficiary. The relatively scant existing literature suggests small to no impact on the marriage and fertility of the transfer recipient, with suggestive evidence of small declines in both outcomes for female school-age beneficiaries. New research on CCTs that directly condition on marriage, as well as additional longer term evidence, will allow for more robust conclusions to be drawn.

Introduction

Conditional cash transfers (CCTs) have become an important policy tool in developing countries and largely aim to improve children's health and schooling outcomes. CCTs are typically targeted at poor households with infants and children and involve regular cash payments to the household conditional on a certain set of behaviors. These behaviors usually involve investments in children's schooling and health such as regular school enrollment or preventive health care visits. A large and empirically well-identified body of evidence has demonstrated the ability of CCTs to improve schooling and health outcomes in developing countries (see Fiszbein and Schady (2009) for an extensive review).

CCTs may also influence other outcomes that are not directly related to the condition including marriage and fertility. These effects may be seen both among the transfer recipients, who are frequently the adult women in the household (i.e., mothers of the target school-aged children or infants or pregnant women), the eligible children, or even among their ineligible siblings. This article first provides the theoretical foundations for why CCTs may affect marriage and fertility, and then discusses the existing evidence on the influence of CCTs on marriage and fertility, as well as a brief discussion of evidence on the impact of other types of pseudoconditional transfers (in-kind transfers, school uniforms, and scholarships) on these outcomes.

Theoretical Foundations for the Impact of CCTs on Marriage and Fertility

From a theoretical perspective, the impact of a CCT on both marriage and fertility is ambiguous. Focusing first on fertility, the increased income to the household makes it more affordable to have an additional child of the same schooling level, thus potentially leading to an increase in fertility (Schultz, 1997, 2004). Moreover, since many CCTs have certain benefits that are provided per child, households can increase benefits by having more children (Steklov et al., 2007). On the other hand, the classic quantity–quality trade-off (Becker, 1960; Becker and Lewis, 1973) suggests that if quantity and quality are substitutes in the parents' utility function then increased quality of children reduces demand for more children (Rosenzweig and Wolpin, 1980). If CCTs increase the quality of children (through increased schooling or improved health), this could lead to a corresponding reduction in fertility (Schultz, 1997). That said, the transition from high quantity/low quality to low quantity/high quality typically occurs over many generations, so it is unclear to what extent short-term influxes of cash will have, or in more established programs, whether enough time has passed since the onset of these programs to realistically expect to see any change (Steklov et al., 2007). There may also be effects on fertility through the supply side component of the CCT, if the CCT includes health-related conditions, through, for example, increased knowledge about contraception or breastfeeding (Steklov et al., 2007).

In terms of marriage of the household head, effects may differ depending on whether you are married or not at the onset of the program. For couples that are married, the increased income to the household may reduce stress and conflict over resources within the household, thus increasing the likelihood of a marriage staying together. On the other hand, the CCT might increase marital dissolution as a result of increased empowerment of the women (women are often the recipient of the transfer) or through increased conflict in the household over how to spend the transfers (Bobonis, 2011). For single individuals' eligible for the transfer, they may become more attractive in the marriage market due to the increased income (Bobonis, 2011). In addition, given the strong focus of these programs on children, CCTs might increase the desire of single individuals to form families, thereby increasing marriage rates (Steklov et al., 2007). Overall, the theoretical underpinnings suggest that the direction of the impact of a CCT on marriage and fertility of the household head is uncertain and will likely depend on a variety of factors related to the country and the program.

For school-age females of childbearing age, CCTs raise the opportunity cost of getting married and/or having a child. In the short run, because marriage and schooling are mutually exclusive in many settings and pregnancy usually leads to dropping out of school (at least missing school for some period), the occurrence of either would lead to a loss of income for the family. It should be noted that while it is the

young women who have to abide by the condition to attend school regularly, it is usually the parents who receive the cash transfers. Under certain circumstances, this may lead to no changes in the opportunity cost of marriage or childbearing for the school-age child and, in fact, may make some of them worse off, if their disutility from schooling is sufficiently high. We abstract from these intrahousehold issues in this article and assume a unitary model of the household. Schultz (2004) argues this point more formally by stating that the cross-price elasticity effects of CCT programs should reduce demand for substitutes for children's schooling. Therefore CCTs should, on average, delay marriage and childbearing, which can lead to reductions in total fertility. In the longer run, CCTs can cause further reductions in childbearing by either changing fertility preferences of young women and/or by changing the opportunity cost of the marginal child (due to increased earning potential through increased schooling). Hence, CCT effects on school-aged female beneficiaries are more straightforward: we should observe delays in teen pregnancies and marriages in the short run as well as reductions in total fertility in the longer run as a result of CCT interventions.

Empirical Evidence on the Impact of CCTs on Marriage and Fertility

The knowledge base on the impact of CCTs on marriage and fertility is fairly limited with only six peer reviewed articles looking at the marriage and fertility of the adult female in the household and six peer reviewed articles on the marriage and fertility of the school-aged children. The search strategy for this article utilized Scopus and Google Scholar and utilized the search terms cash transfer and Marriage or Fertility. References of the initially found manuscripts were also checked, and key researchers in the field were contacted to confirm that no key resources were missing. There are two main reasons for this limited body of evidence. First, the majority of evaluations of CCT programs focus on measuring impacts directly related to the condition(s), and do not collect data on indirect effects. Second, and particularly in the case of school-age children, the expected impacts on marriage and fertility will likely only manifest themselves in the longer term and many of the existing studies of CCTs are not set up to evaluate longer term impacts, or the programs are too new to evaluate these longer term impacts.

Marriage and Fertility of the Adult Female

As mentioned in the previous section, the direction of the impact of CCTs on marriage of the adult female is ambiguous: the additional income in the household may relieve stress and decrease the likelihood of divorce; while on the other hand, the transfer (particularly when transferred directly to the women) may increase her bargaining power within the marriage and increase the likelihood of the marriage dissolving. There are only two papers that we could find in the literature that examines this question. Bobonis (2011) investigates the impact of CCTs on marital transitions using data from the PROGRESA program in Mexico. PROGRESA (now called *Opportunidades*) was established by the Mexican government in 1997, and provides transfers to the adult female in poor households conditional on children's school attendance and preventive health checks. Utilizing data from the initial randomized phase-in of the program from 1997 to 1999, Bobonis (2011) finds that the overall share of women in a marital union did not change as a result of the intervention, but that there was increased turnover (increase of 0.32 percentage points in the intervention communities over a base of 0.47%). Steklov et al. (2007) mentions that they find no impact of Programa de Asignación Familiar (PRAF), a CCT in Honduras, on marriage, but do not show the results. Bobonis (2011) also finds increased formation of unions among program-eligible mothers who were not in a relationship at baseline. Overall, Bobonis (2011) concludes that in the short-term marriage transitions, as opposed to marriage rates, are affected by PROGRESA. However, ultimately the impacts are fairly small, and the author is restricted by the short time frame of the analysis. Perova and Reynolds (unpublished manuscript), examining Bolsa Família in Brazil, also finds no impact of the program on marriage rates; however, similar to Bobonis (2011), they find that the number of separations have risen as Bolsa Família has expanded.

As with marriage, the impact of CCTs on fertility of the adult female head is also ambiguous. CCTs may increase fertility due to increased resources for the household or if higher benefits are provided to larger families. On the other hand, if CCTs lead to increased bargaining power of the women or an emphasis on quality of children, over quantity, fertility may decrease. Once again evaluating PROGRESA, Schultz (2004) finds no differences in the probability of birth in the 6 months prior to November 2009 (about 2 years since the start of the program). Feldman et al. (2009) using a hazard model finds no impact of PROGRESA/Opportunidades on birth spacing (both after 2 years and after 6 years), although they do find short-term impacts on contraceptive use. One possible reason for this lack of effect is the phase-in experimental design that restricted treatment/control comparisons to a relatively short window – as the control groups received treatment with a delay of approximately 2 years.

Stecklov et al. (2007) also look at the impact of PROGRESA on fertility alongside analysis of two other programs in Latin America: PRAF in Honduras and Red de Protección (RPS) in Nicaragua. The authors utilize a measure of fertility that takes on a value of one if the adult woman in the beneficiary household gave birth in the 12 months preceding the survey. Exploiting the randomized implementation of all three of these programs, and utilizing difference in difference estimates, the authors find no short-term impacts (approximately 2 years after the start of each program) on fertility of PROGRESA or RPS, but do find that PRAF leads to an increase in fertility of 1.7 percentage points (or 45% of the decline of 3.8 percentage points in the control group between the pretreatment and posttreatment period), statistically significant only at the 10% level. The authors utilize an alternative specification that defines fertility (before and after the treatment) as having given birth during the past 12 months or being pregnant. The effects for PROGRESA and RPS are again zero, while the effect for PRAF is approximately 4 percentage points, significant at the 1% level. The authors attribute these differential effects to key

elements in the design of the programs related to eligibility and particular whether or not the roster was 'open.' They define a roster as open, if households can become eligible for a component of the program by changing household composition after the onset of the program through, for example, having an additional child. Both PROGRESA and RPS were for the most part closed programs, but the PRAF roster could change in initially targeted communities, thus potentially incentivizing childbearing. All three programs do, however, have limits on the total amount that can be transferred to a given household.

Todd et al. (2011) also look at the impact of RPS on fertility 4 years after the start of the program and find no impact of the program on whether or not the household had given birth in the past 30 months. Note that the control group started receiving treatment 3 years after the start of the program, so the impact estimates are measured off of the differential exposure of 3 years. Utilizing a hazard model, however, the authors do find that the program reduced the odds of a birth occurring by 32% and that the impact is greater for women with more children. The authors suggest that this finding is consistent with an increase in birth spacing and with CCT programs having subtle impacts on household fertility decisions.

Overall, the evidence suggests that the impact of CCTs on fertility and marriage of the household head is negligible; however, one should be careful in using this as conclusive evidence that CCTs have no impact on these outcomes due to a number of important limitations. First, the body of evidence consists of six papers covering three different programs. Second, the analysis is largely measuring short-term impacts, and one might expect impacts on fertility and marriage to only play out in the longer term. Further research from additional CCT programs as well as longer term analysis is needed to fully understand the impact of CCTs on marriage and fertility among adults in beneficiary households.

Marriage and Fertility of the School-Age Children

Through its effects on health and schooling, CCTs also have the potential to impact the marriage and fertility outcomes of school-age children in beneficiary households. Exploiting the randomized design, and using a probit estimation strategy, Schultz (2004) looks at the short-term impacts of PROGRESA on the likelihood of having given birth in the past 6 months. Focusing on 14- to 18-year-old girls prepared to enroll in secondary school, the author finds no significant impact of the program on fertility. The author does finds that increased school enrollment is associated with decreased fertility among this group, but the finding is based on enrollment being instrumented by program eligibility. It may not be entirely appropriate to assume that a CCT program affects the likelihood of births only through its effect on school enrollment for school-age females. Darney et al. (unpublished manuscript) use multiple rounds of a population-based survey and matching techniques to examine the effect of exposure to Opportunidades on pregnancy among 15- to 19-year-old females. The authors do not find any evidence that the program reduced the odds of becoming pregnant. However, the authors are focusing on the impacts of Opportunidades above and beyond the effect of the program on education. If the entire effect of Opportunidades on fertility was via improvements in schooling, it would not be captured in their estimation strategy. Using a difference in difference estimation strategy Behrman et al. (2009) look at the medium-term impacts of PROGRESA/Opportunidades on marriage. Using data from 2003, and comparing those who resided in a locality that became eligible for treatment in 1998 versus those in localities that became eligible in 2000, they find no overall impact of the program on the marriage of boys or girls who were 9–15 when the program started. The authors do, however, find suggestive evidence that youth with early exposure to the program are delaying marriage. (Gardner and Reynolds (unpublished manuscript) examine Bolsa Família and find no reductions in fertility among teens.

Using a randomized evaluation, and looking at a baseline sample of 13- to 22-year-old, never-married schoolgirls in Malawi, Baird et al. (2011) find no impact of CCTs on marriage and fertility. Despite the fact that school enrollment and marriage are practically mutually exclusive in this setting, the improvements in schooling among the CCT group were too small to lead to significant changes in marriage and pregnancy at the end of the two-year program. Moreover, girls who dropped out of school, and thus were not receiving the transfer, were just as likely to be married as the control group. Interestingly, the authors also find large and significant declines in marriage and pregnancy in the experimental study arm receiving unconditional cash transfers (UCTs). While there was little schooling improvement in this group compared to the CCT arm, the income effect among those who dropped out of school during the program seems to be responsible for the decline in marriage and pregnancy. Using data from the same experiment, but focusing on girls who were not enrolled in school at the start of the intervention, Baird et al. (2009) find large short-term impacts of the intervention on marriage (a reduction of more than 40%) and on fertility (a reduction of more than 30%). The large effects in this group are likely due to the sizable schooling effect among this group – baseline dropouts in the intervention group were 3–4 times more likely to be in school than their counterparts in the control group.

IEG (2011) evaluates the Punjab Female School Stipend Program in Pakistan, which started in 2003, and provided quarterly cash transfers of around $10 to families of girls enrolled in middle school with the condition that they attend at least 80% of classes. The program also includes a supply component and was extended to high-school girls in 2006. Utilizing quasiexperimental methods and looking at the impact of the program after 4 years, the authors find no impact on the probability of girls of age 15–19 years being legally married, but do find that after the program started girls in stipend areas were likely to marry about 1.2 years later. In terms of fertility, the authors focus on 17- to 19-year-old girls and find no impact of the program on the probability that the girl has given birth, but do find that girls exposed to the program have, on average, 0.3 fewer children. IEG (2011) also finds relatively large impacts on enrollment (between 14 and 28 percentage points), which may partially explain these impacts.

Overall, the empirical results suggest that CCTs do have the potential to reduce the marriage and fertility of the school-age participants; however, impacts of the program on schooling must be large enough to drive significant changes in these outcomes. Furthermore, the possibility exists that UCTs may also be effective in delaying marriage and pregnancy among adolescent girls and young women (Baird et al., 2011). Again, as with the effects of CCT programs on the marriage and fertility of adults in beneficiary households (or parents of eligible children), further research is needed on longer term effects of these programs to fully understand the impact.

While this section has focused on the impacts of traditional health and schooling CCTs on marriage and fertility, there are two ongoing evaluations of programs that offer cash to families conditional on girls not getting married until the age of 18 years. The International Center for Research on Women (ICRW) is in the process of evaluating the Apni Beti Apta Dhan (ABAD) program in India. Starting in 1994, the ABAD program dedicated bonds to newly born girls in the Indian state of Haryana that can be cashed out when the girl is in the age of 18 years conditional on the girl being unmarried (ICRW, 2013). The first girls turned 18 years in 2012, thus presenting the first opportunity to assess whether the program delayed marriage. Results are expected in 2015. Field and Glennerster (2013) are in the process of evaluating the Kinshoree Kontha project in Bangladesh. One of the intervention arms involves a direct incentive to delay marriage until the legal age of 18 years. Girls aged 15–17 years in the intervention arm are eligible to receive 16 l of cooking oil per year on the condition that they remain unmarried, an amount large enough to cover the financial cost associated with delaying marriage. Results from this study are also pending.

Impact of Other Forms of Conditional Transfers on Marriage and Fertility

The focus of this article is on the impact of CCTs on marriage and fertility; however, there are other conditional transfer programs that use instruments other than cash that are worth briefly discussing. Das et al. (2005) define any program requiring a specified course of action to receive a benefit (cash or in-kind) as a CCT. Their definition is broad enough to include workfare programs (cash conditional on working in a program for a given wage rate) and consumption transfers (in-kind transfers). They argue that these are conceptually identical to CCTs, with in-kind transfers being interpreted as cash conditional on the purchase and consumption of the relevant quantity. We discuss findings from three such studies below.

Duflo et al. (unpublished manuscript) evaluate the impact of the Education Subsidy program in Kenya, a program that provided two free school uniforms to upper primary students over the last 3 years of primary school, thus subsidizing the cost of education. The authors find that the likelihood of having a child declined by 2.7 percentage points (17%) after 3 years and 4.4 percentage points (13%) after 5 years among girls in program schools. The authors also find significant declines in marriage (of 20 and 11%, respectively). After 7 years, the impacts on fertility had disappeared, but there was still a 10% decline in marriage rates (significant at the 10% level).

Angrist et al. (2002) investigate the impact of a school voucher system in Colombia, where recipients are determined via a lottery, which partially covered the cost of private secondary school for students who maintained satisfactory grades. Three years after the lottery, winners were significantly less likely to be married or cohabiting, although since these individuals were only 15 marriage rates were low overall (at 1.6% in the control group). There were no impacts on fertility.

There are also noncash incentive programs that directly target fertility. For example, Ashraf et al. (unpublished manuscript) examine an intervention in Zambia, where married women received vouchers for easy access to modern contraceptives – either alone or with their husbands – compared to a control group who received no intervention. They find that while women who received vouchers alone increased their use of concealable forms of contraception by 38% and reduced unwanted births by 57%, there was no effect on unwanted births among women who received the 'couples' treatment. They argue that increasing the supply of contraceptives (or making access to contraceptives easier) may not have any impact on fertility unless accompanied by changes in *de facto* spousal consent requirements.

Conclusions

This article has investigated the existing evidence on the impact of CCTs on the marriage and fertility of the transfer recipient, typically the adult female in the household, as well as of the school-age beneficiary. For the adult female, from a theoretical standpoint, the direction of the impact on both marriage and fertility is ambiguous. For school-age beneficiaries, theory would suggest that both marriage and fertility would decrease as a result of the program, due to an increase in their opportunity costs, as well as through the effect of increased schooling in the longer run.

The extant empirical evidence suggests at most a limited impact of CCTs on the marriage and fertility of the adult female in the household. Evidence from one program, PRAF in Honduras, suggests that fertility may have increased by approximately 2 to 4 percentage points in program areas largely due to a program design that incentivized childbearing. Outside of this one case, there is no evidence that CCTs change the total number of children, but there may be slight effects on the timing of childbearing and birth spacing. In terms of marriage, there is no evidence that overall marriage rates change as a result of CCTs, but evidence from both Mexico and Brazil suggest that CCTs may increase marriage turnover.

Turning to the school-age female beneficiaries, the overall empirical evidence suggests that CCTs do lead to small declines in fertility and marriage. Short-term evidence from PROGRESA largely shows no impact of the program on fertility, but longer term estimates suggest that individuals with early exposure to the program are delaying marriage. Evidence from Malawi is mixed, with large impacts on marriage and fertility for young women who were out of school at baseline and no impacts for girls who were in school at baseline. The authors attribute this result to the large impact of the program on education for the former group. In Pakistan the authors also find impacts of the

program on marriage and fertility, once again likely due to the large impact of the program on schooling. There is also evidence that other types of transfer programs, such as education subsidies, may also influence marriage and fertility.

Given the general scarcity of evidence on this topic, the readers should be cautious in interpreting our summary. In particular, it is important to keep two things in mind: First, the existing evidence comes from the evaluation of a small number of studies compared to the full scope of CCT programs that exist across the world. One of the reasons for this, as mentioned earlier, is that the majority of evaluations of CCT programs focus on measuring impacts directly related to the condition(s), and do not collect data on indirect effects, which is where marriage and fertility fit in. Second, the expected impacts on marriage and fertility will likely only manifest themselves in the longer run and many of the existing studies of CCTs are not set up to evaluate longer term impacts, or the programs are too recent to evaluate these longer term impacts. Given that CCTs are one of the most rigorously evaluated social protection programs, the existing body of evidence is likely to grow substantially in coming years to allow for a more robust understanding of the impact of CCTs on marriage and fertility.

Abstract

Confabulation, a form of false memory, has been puzzling clinicians and academics since the 1880s. To date, limited consensus has been reached regarding the definition, classification, differential diagnosis, and cognitive mechanisms underlying this disorder. Three main explanatory frameworks have been proposed, each putting forward and testing different predictions regarding the psychopathology and clinical course of confabulation. The present article reviews theoretical and empirical developments in the topic and considers their implications for the definition and classification of confabulation.

Description of Confabulation

Definition and Features

Confabulations are false memories, either because they are entirely or partially incorrect in themselves, or because they consist of real memories jumbled up and retrieved out of context (Kopelman, 2010). The content of confabulated memories is usually autobiographical and unintentional; the patient is usually unaware of the condition (Burgess and Shallice, 1996). Confabulations often compel the person to act upon them (Schnider, 2001). Confabulation is a debilitating condition: the person may self-discharge from hospital against medical advice, and social support networks are often further strained as relatives suffer unjustified or even paranoid accusations and struggle to appreciate their unintentional nature. Confabulating patients lack insight into their false memories, but may have limited awareness of other memory difficulties.

Classification

Several classifications have been suggested (Berlyne, 1972; Feinberg and Roane, 1997; Gilboa and Moscovitch, 2002). Early classifications distinguished between 'momentary' confabulations (plausible confabulations based on reality) and 'fantastic' confabulations (without basis in reality, often with a grandiose theme) (Berlyne, 1972). A widely used classification distinguishes between 'provoked' versus 'spontaneous' confabulations (Kopelman, 1999). Provoked confabulations arise in response to a challenge to memory (e.g., prompted by orientation or memory tests), whereas spontaneous confabulations arise in the absence of any external trigger and the person often acts upon them (e.g., a hospital in-patient who searched anxiously for his uniform thinking erroneously he was on army maneuvers).

More recently, Schnider distinguished behaviorally spontaneous confabulations from three other types of confabulation (Schnider, 2008):

- intrusions – described as 'simple provoked confabulations';
- momentary – plausible, semantic, or autobiographical false verbal statements which may arise spontaneously during conversation or be directly provoked by questions;
- fantastic – confabulations with no basis in reality; sometimes difficult to distinguish from elaborate momentary confabulations.

According to Schnider, behaviorally spontaneous confabulations appear without external trigger and in this way they differ both from false recognition during memory tests and from provoked confabulations, both of which arise in response to a cue. In addition, while provoked confabulations are associated with a variety of lesions and can happen even in healthy people, spontaneous confabulations are only associated with lesions in the orbitofrontal cortex (OFC) or anterior limbic areas connected with the OFC (Schnider, 2003). Behaviorally spontaneous confabulations are also different from fantastic and from momentary confabulations, in that neither momentary nor fantastic confabulations direct behavior. However, in a later article Schnider concluded that behaviorally spontaneous confabulations do share some features with both momentary and fantastic confabulations (Nahum et al., 2012). Other authors have argued that there is no clear distinction between spontaneous and provoked confabulations: moreover, these often co-occur in the same patient (Gilboa et al., 2006; DeLuca, 2009).

Features of Behaviorally Spontaneous Confabulation

According to Schnider, the main characteristic of behaviorally spontaneous confabulations is that people believe strongly in their confabulations and feel compelled to act on them. "For the patients, confabulations are the honest narrative of their perceived reality, rather than invented stories" (Schnider, 2003). In most cases, the person is simply re-enacting an old habit (Schnider, 2008; compare Dalla Barba and Boisse, 2010).

Confabulations can be traced back to true events (Schnider, 2003). Other themes, such as fantastic and semantic (or general knowledge), have been reported in patients with this syndrome, and reduplicative misidentification (such as thinking that one is in two places at once) is often present, but these are not consistent features of spontaneous confabulations (Schnider, 2008; Kapur and Coughlan, 1980).

The syndrome is also characterized by amnesia and disorientation, although some confabulators have demonstrated normal memory function. Orientation to person (i.e., one's

own identity) often resumes once the patient is out of the confusional state (Schnider, 2008).

Differentiation and Etiology

The precise specification of confabulation has led to intense controversy. Some authors distinguish between false recall and confabulation (Schacter et al., 1998; Gilboa and Moscovitch, 2002). False recall usually refers to nonpersonal information studied postinsult, whereas confabulations usually refer to preinjury autobiographical knowledge; although confabulations about semantic material or general knowledge have also been observed (Dalla Barba et al., 1999; Kopelman et al., 1997).

The differentiation between confabulations and delusions remains unresolved. Some authors think confabulations are best understood as disorders of memory, whereas delusions are viewed as disorders of thought (DeLuca, 2000, 2009; Kopelman, 2010). Other authors suggest they share underlying cognitive deficits (Johnson and Raye, 2000; Turner and Coltheart, 2010; Fotopoulou, 2010). Spontaneous confabulations are often held with strong belief, not amenable to change, and often of bizarre content; on this basis, it has been proposed recently that they are best viewed as delusional beliefs, and therefore only provoked confabulations qualify as genuine confabulations (Coltheart and Turner, 2009: p. 181; Turner and Coltheart, 2010). Conversely, some authors have proposed that only spontaneous confabulation constitutes a specific neurological syndrome observed in clinical populations; they have argued it differs from provoked memory lapses, which can occur in the general population (Kopelman, 1999; Schnider, 2008).

The etiology of confabulation is varied; the syndrome has been observed following anterior communicating artery aneurysm (ACoA), tumors, encephalitis, traumatic head injury, and Korsakoff syndrome (Schnider, 2008). In addition, confabulations have been described in the context of schizophrenia (Nathaniel-James and Frith, 1996), degenerative disease (Dalla Barba et al., 1999), and confusional states (Kopelman et al., 1997; Box et al., 1999). However, spontaneous confabulatory errors are often distinguished from lapses arising from confusional states (DeLuca, 2000; Schnider, 2008).

Brain Pathology

Most authors view the ventromedial prefrontal and OFC as the critical areas where pathology is associated with spontaneous confabulation (Gilboa and Moscovitch, 2002). Schnider (2008) has argued that the critical area is specifically the OFC or areas directly linked to it. Medial ventrocaudal (Broadman Area 25 (BA25)) and basal forebrain have also recently been associated with 'confabulatory-type errors' (Turner et al., 2008b). The medial rostral prefrontal cortex (BA 9/10) has been found to be critical for remembering self-generated material (Turner et al., 2008b). Evidence derived from positron emission tomography (PET) scan investigations pointed to BA13 and BA10 as crucial areas for monitoring memory outcomes, and an impairment of monitoring has been postulated as an essential mechanism underlying confabulation (Schnider, 2008; Schnider et al., 2005; compare Moscovitch and Winocur, 2002).

Early Explanations and Theoretical Models of Confabulation

Many models have attempted to explain the underlying psychological deficits that are critical in the appearance of confabulations. At present at least three types of hypotheses are being followed: (1) 'temporality' hypothesis; (2) 'strategic retrieval' hypothesis, and (3) 'motivational' accounts (Kopelman, 2010).

Current models of cognitive mechanisms underlying confabulations drew ideas from earlier models or explanations.

Temporality Accounts

Early models proposed that confabulations were a function of a basic amnesic deficit coupled with a distorted sense of time. This explained why confabulators often think past events are occurring in the present. For example, Korsakoff (1889, cited in Kopelman, 1999; Schnider, 2008) observed that confabulations were often based on the person's past events and prompted the patient to act upon them. Korsakoff's (Schnider, 2008; Kopelman, 2010) model was based purely on clinical observation, but the distorted temporality hypothesis was later developed by several authors, who have provided more detailed explanations based on well-controlled experiments (Schnider, 2008).

Strategic Accounts

Various early authors noted that in order for confabulations to appear there must be a monitoring deficit that allows incorrect memories to be outputted as correct (DeLuca, 2009; Schnider, 2008). These ideas were later developed into more detailed explanations (Burgess and Shallice, 1996; Gilboa and Moscovitch, 2002). These theoretical explanations were primarily concerned with deficits in memory specification, formation, and/or verification processes that give rise to confabulations.

Motivational Accounts

Early motivational theories of confabulation can be divided into at least three distinct types. The first type of early motivational account, the 'gap-filling' hypothesis, is perhaps the oldest 'compensation' theory of confabulation. According to it, confabulation occurs as a purposive act contrived by the patient to spare him from the embarrassment of not being able to remember the events of his life (Bonhoeffer, 1901; cited in Talland, 1961). This view has been criticized as patients seem genuinely unaware of their memory errors (anosognosic) and thus it seems clinically invalid to describe them as consciously attempting to conceal what they seem to ignore, i.e., their memory deficit. Also, many confabulating patients did not show a tendency to increase their confabulation rate when they were confronted with questions to which they did not know the answer (e.g., Dalla Barba et al., 1997; Kopelman et al., 1997; Mercer et al., 1977; Schnider et al., 1996).

Pick (1905, 1915 in Talland, 1961) and Korner (1935 in Talland, 1961) noticed that the statements of confabulating patients can be easily steered by leading questions. Thus, they

argued that 'suggestibility' has a causal role in the gap-filling forms of confabulation. Moreover, Johnson and colleagues (1997) reported a patient who among other deficits showed 'a propensity toward detailed imaginations' (Johnson et al., 1997: p. 203). In this sense, suggestibility may be seen as part of one's personality structure, or more generally an individual predisposition to external suggestion and compliance. This approach is similar to the second set of motivational theories, reviewed below.

According to the second kind of theories, certain personality traits may distinguish between patients who are likely to develop confabulation and those who do not. Berlyne (1972) for example, observed that five out of the seven Korsakoff patients who he studied were premorbidly extraverts. In a study on confabulation in the context of senile dementia, Gainotti (1975) conducted what remains until today the most systematic study of this hypothesis (see also Conway and Tacchi, 1996). He asked relatives to describe the premorbid personality of 8 confabulating patients and 22 nonconfabulating control patients. The results indicated opposite personality traits between the two groups.

Some psychoanalytically oriented clinicians recognized in the content of confabulation the mark of psychodynamic mechanisms (for reviews see Berlyne, 1972; Betlheim and Hartmann, 1951; Davidson, 1948). For example, some authors suggested that the individual's wishes and interests guided confabulation in the same way as they controlled dream fantasy (Berlyne, 1972; Betlheim and Hartmann, 1951; Van der Horst, 1932). In addition, Lidz (1942 in Talland, 1961) had discussed confabulation as a response to overwhelming anxiety and Zangwill (1953 in Berlyne, 1972) had conceptualized confabulation as a defense against 'a catastrophic reaction,' i.e., a depressive reaction to one's illness.

The hypothesis that confabulation is a form of 'psychological denial,' i.e., a compensatory coping mechanism instigated by excessive anxiety, was mostly advanced and crystallized in Weinstein and colleagues' (for a review see Weinstein, 1996) formulation of the 'defense' hypothesis. Weinstein and colleagues claimed that although confabulations frequently involve references to past events, they are to some degree, symbolic representations, dramatizations, or explanations of some current personal experience, preoccupation, or disability (Weinstein et al., 1956). These symbolic functions are based on kernels of awareness of deficit, i.e., confabulations implicitly express illness preoccupations and anxieties, which the patient is not capable of fully appreciating and explicitly expressing. Finally, the symbolic function of confabulation seems to have an ultimate adaptive role. Weinstein observed, following Bonhoeffer (1901, cited in Weinstein, 1996) that during the narration of confabulations, patients become engrossed in detail, lose their previous irritability, and then appear utterly relaxed.

Although these views have highlighted the positive aspects of confabulation, there has been little experimental evidence in their support. Moreover, these coping mechanisms are considered independent of the specific neuropathological features of the syndromes they aim to explain. Thus, their explanatory power with regards to the syndromes themselves is limited.

Nevertheless, it is important to emphasize that not all psychodynamic authors considered emotional mechanisms in isolation. Instead, some regarded the emotional manifestations of confabulation as the direct consequence of dysfunction of the normal mechanisms of remembering (Betlheim and Hartmann, 1951).

In the last two decades, as the study of emotions was included among the mainstream interests of cognitive neuropsychologists and neuroscientists (see Fotopoulou, 2010), several neomotivational accounts emerged (Conway and Tacchi, 1996; Fotopoulou et al., 2004). These are complementary to the temporality and strategic retrieval models outlined later: they do not make claims about the cognitive deficits that lead to the emergence of confabulations per se; instead they attempt to explain the emotional factors that are dysregulated by such cognitive deficits and hence influence the content and form of confabulations.

Executive Dysfunction

Several authors have suggested that executive dysfunction could explain confabulation independently of amnesia (Kopelman, 1987; Kapur and Coughlan, 1980; Benson et al., 1996). For example, in one study two patients underwent a neuropsychological assessment before and after they recovered from confabulation. At retest both patients showed improvement on executive tests in parallel with decreased confabulations, but their amnesia scores remained unchanged at the severe level of function. The authors concluded that frontal dysfunction, and not amnesia, was the critical deficit associated with confabulations (Kapur and Coughlan, 1980; Benson et al., 1996; but see DeLuca, 2009). However, behavioral experiments have indicated that executive dysfunction did not distinguish between spontaneous confabulators and other patients with amnesia, nor did it parallel recovery from confabulation (Schnider, 2003). In addition, confabulation has been described in the apparent absence of executive dysfunction (Burgess and Shallice, 1996; Johnson et al., 1997; Dalla Barba et al., 1999).

Current Main Theories of Confabulation: Temporality Models

Korsakoff, Tiling, Van der Horst, and Talland had noticed disturbed temporality or chronology as a salient feature of confabulation (Schnider, 2008; Kopelman, 2010; Talland, 1965). Two models have derived from early temporality explanations: a 'disturbed temporal consciousness' model and a 'temporal context confusion' (TCC) model.

Disturbed Temporal Consciousness

Disturbed temporal consciousness is one of the current explanations for the appearance of confabulations (Dalla Barba et al., 1999). This model proposes the following explanation for confabulations. Confabulators may be aware of a personal past, present, and future which is distorted. Temporal consciousness is strongest for well-established knowledge. Consequently, when memory traces are weak, temporal

consciousness is framed by more stable memories: semantic knowledge. Therefore, when prompted, confabulators are likely to answer with memories or plans corresponding to well-rehearsed memories or habits (Dalla Barba, 2009; Dalla Barba and Boisse, 2010).

Dalla Barba's model is unique in that it is the only explanation that proposes a conscious mechanism of confabulation. He has criticized other models for putting forward explanations based on unconscious mechanisms which are not scientifically verifiable (Dalla Barba, 2009).

At present, Dalla Barba's Confabulation Interview is the only established protocol for exploring confabulations across episodic, semantic, personal, and nonpersonal domains (Dalla Barba, 1993). Moreover, an updated version of this interview also explores confabulations regarding future plans (Dalla Barba et al., 1997).

Temporal Context Confusion

The distorted temporality characteristic of confabulators is the focus of one of the most influential models to date: the TCC model (Ptak and Schnider, 1999). Schnider believed confabulators often had a distorted sense of time independent of memory deficits (Schnider, 2008: p. 230). His model refers specifically to 'behaviorally spontaneous confabulations' (Schnider, 2008). These are false memories that occur in the absence of an external trigger and that direct behavior.

Clinical Evidence for TCC

Schnider's model was developed from a series of elegant experiments employing a TCC task. The TCC task (Schnider et al., 2000a) consists of two runs of a continuous recognition task (run 1 and run 2). The first run measures straightforward storage and recognition. In the second run, however, items that in the previous run were targets become distracters and vice versa. As a result, the targets in the second run suffer intense interference from former targets, and consequently this part of the task cannot be completed relying on familiarity alone. An example of the stimuli used in this task can be seen in Figure 1 (Schnider, 2001).

In a series of investigations, behaviorally spontaneous confabulators performed as well as amnesic controls in the first run of the TCC task, whereas they consistently failed the second part. Schnider and Ptak (1999) initially concluded from these results that spontaneous confabulators were unable to

Figure 1 The experiment. In the first run, subjects see a long series of pictures, among which several pictures are repeatedly presented. Subjects have to indicate picture recurrences. This run measures learning and recognition of new information. The second run is composed of precisely the same picture series, arranged in a different order. Subjects are asked to forget that they have already seen all pictures and to indicate picture recurrences only within this current second run. d1, d2, first presentation of a picture in run 1 and run 2 (distracters); T1, T2, picture recurrences within run 1 and run 2 (targets). Variations of this task with different numbers of runs, items, and intervals were used in our studies. Schnider, A., 2001. Spontaneous confabulation, reality monitoring, and the limbic system–a review. [Review, 70 refs]. Brain Research - Brain Research Reviews 36 (2–3), 150–160. Reproduced with permission from Elsevier.

suppress memories that were currently incorrect. However, this explanation did not accommodate processes such as day-dreaming or creativity. Therefore, this deficit was later reformulated as an inability to 'filter' incoming information that pertains to ongoing reality (Schnider, 2008). Schnider's results with this task have been replicated either totally or partially (Schnider and Ptak, 1999; Schnider et al., 2000a; Turner et al., 2010; Gilboa et al., 2006; Bajo, 2011).

Schnider followed up eight confabulators who performed the TCC task again after 3 years (Schnider et al., 2000a). At follow-up seven out of the eight patients had stopped confabulating, and they performed normally on the TCC task. No other cognitive measures used (i.e., California Verbal Learning Task, a verbal and design fluency task, and the short Stroop test) paralleled the course of confabulation. Therefore, Schnider concluded that TCC was necessary and sufficient to explain the presence and clinical course of confabulation (Schnider et al., 2000a).

Over time significant limitations of the TCC task have been described. Schnider himself described a confirmed confabulator who performed normally on the TCC task. This was attributed to the patient having adopted a conservative response criterion as a strategy in order to cope with the confusion caused by the TCC task (Schnider, 2008: p. 251). Bajo (2011) also found seven confabulators who performed at the control level on this task. Another patient did not confabulate despite abnormal TCC performance. Schnider suggested that perhaps this person's preserved memory function had overridden the effects of TCC, thereby stopping confabulation (Schnider, 2008: p. 251). Gilboa et al. (2006) and Bajo (2011) also found that a group of patients who had suffered ACoA and a group of brain injured survivors with moderate to severe dysexecutive difficulties did poorly on this task despite being free from confabulations. This indicates that although TCC may be sensitive to confabulation, it is not specific to the syndrome. Instead, TCC may be specific to pathology that affects the ventromedial prefrontal cortex (VMFC) (Gilboa, 2010). Indeed, in a recent paper, Schnider and colleagues concluded that TCC alone cannot predict the presence of behavioral confabulation without reference to level of amnesia (Nahum et al., 2012).

Imaging Evidence for Temporality Models

Further reformulation of Schnider's model came from neuroimaging studies. Schnider et al. (2000b) scanned a healthy sample while carrying out a more difficult version of the TCC task. Results showed brain activation during the critical part of the task (run 2) corresponded to the posterior medial OFC (BA13).

Evoked potentials and cortical activation maps showed a striking difference in frontal brain activation between distracters in run 2 and other stimuli. At 200–300 ms after stimuli presentation, processing of distracters in run 2 skipped a stage of cortical synchronization. This early activity occurred even before encoding took place (at 400–600 ms) (Schnider et al., 2002).

One explanation put forward was that activated memories go through a preconscious 'filtering' stage. If memories are not currently relevant, the OFC inhibits cortical synchronization. In this way memories are tagged as either being currently relevant or not, and go on to influence behavior accordingly (Schnider, 2003, 2008: p. 269).

Why should confabulators be so convinced of their false memories even in the face of contradictory evidence? Schnider speculated that confabulations represent a behavioral extinction deficit. He noted that primates with ablations of the OFC had trouble extinguishing responses that are no longer required. Therefore he proposed that perhaps confabulators had difficulty extinguishing memories that are no longer relevant to their current situation.

PET experiments in which healthy participants performed decision-making tasks showed that extinction trials underwent different processing to other trials at 200–300 ms. The areas involved were BA10 and BA13. One explanation was that the OFC acted as an 'outcome monitoring system' signaling the nonoccurrence of a predicted event through cortical activation. Absence of this signal would lead to a false sense that predictions had been met. In the case of confabulators, it would provide certainty that the event recalled was correct (Schnider, 2008: p. 291).

Summary of Temporality Models

In summary, temporal models focus on a strikingly distorted sense of time which is characteristic of confabulations. Clinical experiments suggested TCC was the critical disorder that predicted both the appearance and recovery from confabulation. Imaging experiments suggested the OFC was responsible for early inhibition of cortical synchronization of memories that are not currently relevant. Schnider proposed that confabulations appear when this early 'filtering' or 'extinction' process is faulty.

Aspects of this model do not seem incompatible with some features of strategic retrieval models, which are reviewed next. The basic deficit in confabulation proposed by Schnider is one of faulty monitoring during memory reconstruction (Schnider, 2008: p. 270). Indeed Schnider's 'reality filtering' mechanism is not dissimilar to other filtering processes (Gilboa, 2010); compare Burgess' notion of 'gateway' sited in BA10 (Burgess et al., 2007a,b). In addition, the OFC as an 'outcome monitoring system' resembles the idea that the OFC is involved in 'matching events to internal predictions' (Turner et al., 2008b). However, despite these commonalities, the models have very different emphasis.

Current Main Theories of Confabulation: Strategic Retrieval Models

Early authors (e.g., Korsakoff, Kraepelin, and Tiling) explained confabulations as a combination of amnesia deficits and a monitoring deficit (DeLuca, 2009; Schnider, 2008). Kapur and Benson had highlighted the role of executive dysfunction on confabulation (Kapur and Coughlan, 1980; Benson et al., 1996). The following explanations of confabulation hinge on the dysfunction of specific control mechanisms that operate during normal recollection.

Memory Reconstruction Processes

Many authors view memory as a series of constructive processes, and as such, it is open to errors during memory reconstruction (Schacter et al., 1998; Moscovitch and Melo, 1997). Cognitive mechanisms proposed by these models apply to both normal and abnormal memory. Two key processes of successful memory retrieval have been proposed:

1. Different elements of the information to be retrieved must be bound together in order to produce a coherent memory. Dysfunction of this process leads to source memory deficits, where events are recollected without important details, for example, timing or location in which the event occurred.
2. Similar events must be distinguished from the specific memory to be retrieved. If this does not happen, only the gist of an event would be remembered.

Control Mechanisms Underlying Memory Reconstruction

According to this view, confabulation (of any type) arises as a consequence of dysfunction of one or more executive processes involved in memory reconstruction (Moscovitch and Winocur, 2002; Burgess and Shallice, 1996; Kopelman, 1999). These can be related either to the search strategy or to the monitoring of the retrieved information (Moscovitch and Melo, 1997). Three main strategic retrieval processes are described: 'descriptor,' 'editing,' and 'mediating' processes (Burgess and Shallice, 1996; Burgess and McNeil, 1999; Gilboa and Moscovitch, 2002). Figure 2 depicts this model from the viewpoint of Burgess and Shallice (1996).

1. Descriptor or cue specification processes are responsible for generating internal cues to guide information retrieval. Normally, generic memories are used as default 'starting value templates' to speed up the process of memory reconstruction (Burgess and Shallice, 1996; Moscovitch and Winocur, 2002). They are subsequently refined and modified as they undergo verification (Moscovitch and Melo, 1997). However, in the absence of adequate specifications to guide recollection, these generic 'input templates' are erroneously reported as the target memory (Burgess and Shallice, 1996). The absence of descriptor cues could also result in exaggerated external cueing effects in recollection; this would be the case, for example, of a patient who mistakenly reported she was a member of staff in the hospital in which she was a patient (Kopelman et al., 1997).
2. Editing or monitoring mechanisms are responsible for verification, accuracy checking, and comparison of retrieved memories (Burgess and Shallice, 1996; Moscovitch and Winocur, 2002). Malfunction of these verification processes would mean that retrieval of erroneous material would go unchecked.

Figure 2 Relationship between memory control processes (in triangles) and other memory and cognitive systems. In this model, autobiographical recollection occurs through the action of two processes. An input template (i.e., a generic representation derived from perceptual and cognitive input and pre-existing (semantic) associations) activates key nodes within the long-term store. These nodes are linked by paths of differing associative strength. Recall of semantic information proceeds through activation of these nodes, where a node is a context-independent representation. Autobiographical recollection proceeds through activation of these nodes via a template concurrently with a descriptor process. The descriptor defines a precise set of paths in the net which corresponds to aspects of specific events. Recollection itself is the constant reiteration of descriptors in such a way as to 'explore' the net. The editor detects incompatibilities either within the recall structure or between the original description and the output representation. Resolution of these incompatibilities, impasses, or failures in activation proceeds through problem-solving routines initiated by the mediator, to which the other cognitive systems are enslaved. The products of these supervisory processes are used to form new descriptions. Burgess, P.W., Shallice, T., 1996. Confabulation and the control of recollection. Memory 4 (4), 359–411. Reproduced with permission from Elsevier.

3. Mediator processes are problem-solving processes, not necessarily specific to memory. If retrieval of a false memory is detected, mediating processes would prevent its erroneous output and redirect the search. For example, fantastic confabulations are said to be caused by malfunction of mediator processes which fail to check the general plausibility of the material remembered.

One criticism of the above model is that the monitoring processes proposed are not specific to confabulation – they apply to true memories too; furthermore, they do not distinguish between different types of confabulation (Schnider, 2008: pp. 227–228). A further critique argues that these models rely on nonobservable processes that make verification of these theories difficult (Dalla Barba, 2009). For example, there is a lack of evidence concerning the physiological basis of the monitoring processes described by these models (Schnider, 2008: p. 228). Some retrieval models have been developed without reference to clinical data (Schnider, 2001). Finally, they do not explain the temporal confusion that usually accompanies confabulation (Schnider, 2003).

Cognitive Mechanisms Underlying Confabulation

A recent model has structured the above processes in a different way and extended the above theoretical explanations. Gilboa and colleagues (Moscovitch and Melo, 1997; Gilboa, 2010) proposed that three types of cognitive mechanisms underlie confabulation: (1) 'core' processes, which are essential for the appearance and course of confabulations, and are specific to this syndrome; (2) 'constitutional' processes, which may be necessary but are not specific to confabulations; and (3) 'associated' features, which are not critical for the appearance of confabulations, but may influence their content. Three types of core processes are reviewed below, followed by a summary of constitutional processes and associated features, as proposed by Gilboa and colleagues.

Core Processes

Three core mechanisms are described; the first two are different types of monitoring processes: (1) a 'preconscious feeling of rightness (FOR)'; (2) conscious monitoring mechanisms; and (3) control processes.

1. 'Preconscious FOR' mechanisms appear to be heuristic decision-making processes that verify retrieved memory traces and tag them accordingly very early in the process of retrieval. When these processes break down, false memories may be accepted as correct. In addition, false memories that are autobiographical in nature may direct behavior, because they are held with great conviction. This may be because autobiographical information is both very well established and salient to each individual.
2. Conscious monitoring mechanisms are more thorough verification processes, which take place later in the process of retrieval (Gilboa, 2010; Burgess and Shallice, 1996). Memories are verified against retrieval cues and contrasted with available information. If these mechanisms function correctly, they may overhaul FOR processes and prevent confabulations. Breakdown of conscious monitoring mechanisms may result in fantastic or inconsistent confabulations.
3. Control processes allow us to consider the consequences of reporting the retrieved material and help us decide whether to report it or not. For example, if the cost of reporting a memory is too great should it turn out to be false, the person may decide to withhold it. Even if the other two core mechanisms are faulty, control processes may stop a confabulation from being reported. For this reason, all three core mechanisms must be faulty in order for confabulations to appear.

Constitutional Processes

Constitutional processes (Gilboa, 2010) are those that are usually associated with confabulation, but are not unique to confabulation. Deficits in these processes may be necessary for the appearance of confabulation, but they are not sufficient. For example, a memory deficit seems to always accompany confabulation but it is not specific to this syndrome. Search initiation and cue specification deficits may also contribute to the appearance of confabulation, but can also appear in its absence. In contrast with Schnider (2008), some authors (Gilboa, 2010; Bajo, 2011) claim that TCC may be sensitive but not specific to the presence of confabulation. Failure in this task has been associated with particular brain pathology in the VMFC, rather than with confabulation per se (Gilboa et al., 2006).

Associated Features

Associated features may be present in connection with confabulations but are often absent, therefore they are not considered constitutional to the syndrome. They typically determine the content of confabulation and form part of normal reconstructive function. For example, many confabulations have a self-serving bias (see Fotopoulou, 2010, for a review), but this may not be a universal bias (Metcalf et al., 2010; Bajo et al., 2010). Confabulations often represent 'generic' well-rehearsed memories (Burgess and McNeil, 1999; Dab et al., 1999; Metcalf et al., 2010). These seem to be exacerbations of normal recollection errors and appear in many contexts. Perseveration has also been observed in confabulators, especially in semantic memory (Kopelman et al., 1997), but this seems to be associated with frontal pathology in general.

Imaging Evidence in Support of Strategic Retrieval Models

Strategic retrieval models are based on imaging and behavioral experimental data in support of both monitoring mechanisms and control processes. Imaging data have demonstrated that patients with VMFC lesions skipped an early positive modulation that was present in controls at 240 ms poststimulus (Gilboa, 2010). This appears to be consistent with Schnider's imaging findings which showed an early deactivation (Schnider et al., 2002). Furthermore, Gilboa's patients also lacked a positive modulation that controls showed at a later stage: 350 ms poststimulus. Gilboa (2010) argued that these two results would support the theory that two distinct monitoring mechanisms are critical for the appearance of confabulation: (1) early 'FOR' and (2) late and more in-depth monitoring processes.

Clinical Evidence in Support of Strategic Retrieval Models

Behavioral experiments showed that confabulators seem to report false memories even when the need for cue specification and creating a search strategy are minimized (Gilboa et al., 2006). One confabulating patient made far more errors than controls, despite showing a general conservative response criterion on a free report memory task (she only reported information if she was at least 75% sure it was true, Gilboa, 2010). These results indicate that confabulation is not merely the consequence of a general bias or a response inhibition deficit, but a very specific monitoring deficit (compare Turner et al., 2008a). Confabulations were also associated with an indiscriminate sense of confidence in their veracity, even when they were highly implausible (Gilboa et al., 2006). These findings are consistent with a specific deficit in 'preconscious FOR' as a critical mechanism in the appearance of confabulation.

Evidence for the role of control processes in confabulation has come from a single-case experiment where the confabulating participant was free to withhold answers during the course of free report (rather than structured interview, Gilboa, 2010). This patient seemed unable to stop generating answers, even after she had reported the correct answer. This is consistent with the critical role of control mechanisms in the appearance of confabulations.

Furthermore, using tasks sensitive to confabulation, Gilboa (2010) found delusional patients presented a distinct pattern of response to that of confabulators. In contrast with confabulators, delusional patients showed poor control function, good monitoring ability, and a liberal response bias. They further differed from confabulators in that they did not show a primary memory deficit.

Summary of Strategic Retrieval Models

In summary, strategic retrieval models explain confabulation as a dysfunction of monitoring mechanisms that operate during normal memory reconstruction. They do not discriminate between different types of confabulation. Core cognitive processes that are critical and specific to the appearance of confabulations include: (1) an early FOR about a memory; (2) a more in-depth monitoring process; and (3) control mechanisms that allow the individual to decide whether to report a memory or not, irrespective of its perceived veracity. All three must be impaired for confabulations to appear. Constitutional processes may be necessary, but they are neither specific to nor sufficient for the appearance of confabulations. Memory deficits and TCC fall into this category. Associated features have been observed during confabulation, but they are often absent. These may affect the content of confabulation, for example, making it predominantly self-serving or generic (i.e., devoid of detail).

Strategic retrieval models provide the most comprehensive explanation of confabulations. They share a common base with motivational models. Both types of models explain confabulations as distortions of normal memory reconstructive mechanisms. However, motivational models make predictions specifically about the content of confabulations. They are reviewed in the next section.

Current Main Theories of Confabulation: Neomotivational Accounts

Modern motivational theories of confabulation do not regard confabulations as arising from compensatory, motivational tendencies or copying mechanisms per se, but rather from a dysregulation (due to neurocognitive impairment) of the organically predetermined influence of motivation on memory formation. Positive, self-serving biases in memory and cognition are now well established (Sharot, 2011; Walker et al., 2003). Neomotivational models suggest that when irrelevant memory representations are not inhibited and memories are not retrieved in appropriate manner (as the various neurocognitive theories support; Burgess and Shallice, 1996; Gilboa et al., 2006; Johnson and Raye, 2000), motivational factors may acquire a greater role in determining which memories are selected for retrieval and accepted as true (Conway and Tacchi, 1996; Solms, 2000; Fotopoulou et al., 2004; Fotopoulou, 2010; Turnbull et al., 2004, 2005). This lack of affective regulation in memory is attributed to the typically reported damage of the ventromedial frontal cortex in confabulation, which is more generally thought to be responsible for affective regulation (e.g., Bechara et al., 2000).

Fotopoulou and colleagues (2004) further put forward the prediction that the false recollections of confabulating patients should show a self-serving bias that is greater than that typically encountered in the memory distortions of healthy volunteers (see above). The content of spontaneous confabulation has been found to contain mostly positive and wishful descriptions in a number of single-case and group studies (e.g., Fotopoulou et al., 2004, 2008b; Turnbull et al., 2004). A positive bias has also been observed in the provoked confabulations of another patient, elicited during an autobiographical memory interview (Fotopoulou et al., 2007a). In the latter study, the patient's confabulations portrayed a self-representation that was more positive than that depicted in his real memories and those depicted in the memories of matched healthy controls. A further case series showed that confabulating patients were more likely to perform reality monitoring errors, accepting false or temporally irrelevant information as part of their recent past, when the information was pleasant rather than unpleasant (Fotopoulou et al., 2007b). For example, a patient was significantly more likely to falsely claim that he actually remembered winning the lottery recently than to falsely claim that he remembered losing his job. Finally, in a recent prose recall study, confabulating patients ($N = 15$) showed a strong selective bias in recalling negative self-referent stories, in that they recalled such information in a manner which portrayed a more positive image of themselves (Fotopoulou et al., 2008a). This positive bias was not present in stories that were not encoded in a self-referent manner. This study shows that confabulating patients do not have difficulty in processing negative emotions in general. Instead, they show a specific self-related motivational bias in their memory.

The self-related bias has been further explored in clinical studies on confabulation (e.g., Fotopoulou, 2008), as well as confabulation in patients with right-hemisphere syndrome affecting their visuospatial and motor awareness (Fotopoulou et al., 2010; Fotopoulou, 2012). This more general perspective

on illusion, delusions, and confabulations concluded that deficits in higher-order areas such as the VMFC and parietal cortex may lead to dynamic exaggerations of self-enhancement, self-deceit, and self-coherence tendencies in neurological patients (Fotopoulou, 2008, 2012, in press). The latter proposal is consistent with recently emerging, multifactorial models of confabulation that include personal goals and wishful ideation among the critical factors that may determine the retrieval of false memories in confabulating patients (Gilboa et al., 2006; Johnson and Raye, 2000; Kopelman, 1999; Metcalf et al., 2007). Acknowledging the role of emotion in confabulation has also pivotal clinical consequences (see Fotopoulou, 2008, for review). It thus seems that at least some authors have recognized that emotion may have a determining role in confabulation and that only its interaction with the neurocognitive factors yields the total psychological picture of the syndrome.

Summary

In summary, confabulation is a debilitating condition that may cause patients to act according to erroneous beliefs. Available evidence indicates confabulation is associated to pathology in the VMFC. At present, there seems to be little consensus among authors regarding its classification and underlying cognitive mechanisms. In addition to a basic amnesic syndrome, several cognitive and emotional factors that may be responsible for confabulation have been proposed: temporal dysfunction, monitoring dysfunction, and motivational factors. Their specific contribution remains unclear, although it is possible that they all contribute to the appearance of confabulation in some measure. Very few longitudinal investigations have been carried out, thus the course of confabulation is at present relatively unknown. Further investigation of confabulation along these lines would be paramount in order to discover the best way to treat this condition.

Abstract

This article addresses the term 'Confederation', its definition, and notable examples history. Usually, scholars in political science and international relations tend to ignore giving a comprehensive definition to this term, and prefer to interpret it in comparison to 'federation', a term providing a close, but at the same time, very different structure to confederation. The illustrative case studies highlight the specific cultural and political environments in which a confederate structure can arise.

Definition of Confederation and Primary Characteristics

A confederation is an entity in the system of international relations that first appeared as a political organization of independent actors, usually of states or their legal equivalents, created by their will to achieve certain common goals or to unite in certain aspects, without giving up their sovereignty.

Among the main characteristics of a confederation are the following: (1) It is a structure created by volunteer association of several sovereign states with the purpose of achieving common goals. (2) Compared with similar interstate systems, it has a transitory, hybrid character, being less centralized than a federation or a union, aside from imperial structures realized by conquest, colonialism, or hegemonic power; however, at the same time, it is more centralized than a league, alliance, or intergovernmental organization. (3) The confederate form of association is appreciated by its founders because it involves collective security and enhancing efforts for the common good of its members, without the loss of individual sovereignty of any of its components; however, these aspects often can be guaranteed by more loose systems, too, like alliance, custom union, or concert of powers. (4) Creating and joining a confederation depends on the will of the respective state or its equivalent, and the theoretical – and often the practical – possibility to leave the structure by secession. (5) The base of a confederation is represented by a founding act or constitution, adopted through consensual decision of its members. In preliterate societies – like the Native American tribes from before the conquest of America by European colonists – the founding treaty or a constitution is not written but rather is transmitted orally. This fact does not affect the respect for the content of the treaty, as it is based on mutual interests, trust, and common law. Changes made to the common legislation usually requires consensus, and if not consensus, at least a majority vote. (6) A confederation usually has central organs, like a common monarch or president, who represents the structure as a single entity toward other actors of international relations, and also has a parliamentary consultative – a legislative institution – with members serving as the delegates of the component political units of the confederation. Because a confederation is created with the respect of the principle of nonintervention of central organs in the internal affairs of its component units, the decisions taken by central organs have a consultative, recommending character rather than a compulsory one. Often, a central organ acts as judge or mediator in internal disputes, because common security and a reduced level of internal conflicts is one of the main goals of any kind of confederate structure. In this latter case, the decision of the organ of judgment is compulsory and is guaranteed by the common will of the members, or at least by common laws. (7) In the ceremonial plan, central institutions prevail to institutions of its component units – for example, the parliament of the confederation is granted higher publicity and respect than a regional or local decision-making institution. The coercive power of the central organs, however, is nonexistent or minimal, because the base of a confederate structure is the maintenance of sovereignty of its composing members. (8) Political institutions of composing units can delegate a part of their competences to the central organs. This happens usually in the plan of common defense, foreign affairs, and more rarely, certain economic plans –for example, like adopting a common currency or the instauration of a custom union. Generally, among the competences of the central institutions are the coordination and harmonization of policies of component units by providing support in this sense for all of the members. (9) In the case of a confederate structure, central organs act only upon their member units, not over the individual citizens of those member units, too, who owe allegiance first to the state where they live and not to the confederate structure as a whole. As a consequence, becoming a citizen in a confederate structure is possible by being granted a citizenship by one of its component states, a practice common in Switzerland, too, where naturalization is granted by the canton and not by the state of Switzerland. The latter body is only accepting the decision made by competent organs of the respective canton. In case of most of the confederate structures, common citizenship does not exist, but there are exceptions as well, like in case of the historical Canadian Confederation (1867–), the United States during its confederate period (1781–89), or during the Old Swiss Confederacy (1291–1798). In some case, coercion through force brought the end of the confederate structure, as in case of the Confederate States of America (1861–65) in the Civil War, or to the Deutscher Bund/German Confederation (1815–66) in 1867, by the victory of Prussia in the Seven Weeks' War. (10) The confederation as structure grants a common national banner under which its members can act in solidarity or individually, but it does not

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62159-1

create a new political nation. (11) Many thinkers consider that confederation as a structure can represent only a temporary solution and is unviable in the long term, because of its loose structure, and with time, it evolves to dissolution toward a more centralized unitary structure, most likely to a federal one. This was the case for Switzerland, the United States, Canada, and Argentina, whereas other historical confederations have ceased to exist. In proper conditions, a confederate structure can represent a viable long-term solution, and does not have to suffer a metamorphosis in a compulsory way. (12) A series of misnomers exist in case of using the term confederation, usually being confused with a 'federation', which designs a different kind of international structure of state association. The term 'confederation' is the perfect synonym for 'confederacy' or 'confederate states', but the term often is mistaken with other similar ones, having a slightly different meaning. Often, the term 'confederacy' or 'confederation' is used to name a federal structure. On the other hand, international structures that often are unions or federations by definition are acting in practice as a functional confederation. According to John T. Rourke, "the European Union provides a current example of what is, or at least, approaches a confederation" (Rourke, 2001: p. 224). (13) In a functional on long-term confederation, there is a high level of interdependency, or at least a permanent common challenge, which prevents its split or dissolution.

The confederation should not be confused with the federation, which is a structure functioning on similar principles, but in a more centralized way. It also should not be confused with the personal union. In the case of a personal union, the key figure is the common monarch, who is holding the function of head of the state of two or more monarchies, with respect to the internal legislation and cultural heritage of each one monarchy and not the will of these states to come together as a centralized new actor of international relations. Personal unions with a confederate character can exist, however, as was the case of the Kalmar Union (1397–1523), when the sovereign kingdoms of Denmark, Sweden, and Norway were unified through a series of personal unions under a common monarch.

In another approach, it is not incorrect to apply the term confederation to certain tribal confederations, which are manifesting themselves with a prestate structure. At the same time, the term should not be used by its modern definition; starting with the Modern Age, the main actors of international relations are the states themselves. In Ratzel's definition, the state is characterized by three major traits: it has territory, a population, and common institutions (Ratzel, 1897). Premodern tribal structures often had more power and prestige than centralized states did; for them, the state structures were far less important than the organic unity of the community of its members.

The following sections present a series of confederate projects of important thinkers, as well as some historical examples for functioning confederations.

The Issue of Tribal Confederations

Structures with a confederate character existed long before the birth of the notion of modern confederation, in different places and time, throughout all the history. Such examples include the possible – unproved yet – existence of the Thinite Confederacy in Ancient Egypt, lead by Menes, which met its end by the unification of Egypt; the coexistence of the 12 biblical Jewish tribes from Joshua until the appearance of the first king, Saul, which also bears elements of confederacy; and the Etruscan and the Samnite civilizations in Italy until their conquest by the Romans. Some classical examples for tribal confederation can be found in the history of European barbarian people of Antiquity, including the Gauls (Mandubii, Boii, Volcae) and Germanics (Bastarnic or Marcommanic tribal confederations). The best examples for so-called tribal confederations can be found in the case of horseback nomadic people of the steppes, which may have been Mongol, Turkic, or Indo-European by their origin, as well as the Xiongnu, Hun, Yuezhi, Rouran, Onogur, and Uyghur tribal confederations. The early principality of Hungary, until the appearance of the centralized Hungarian kingdom, also can be considered to be a tribal confederation. Most of these tribal cooperation can be called a 'tribal confederation' in certain periods of their existence, but only when they have the characteristics of a veritable confederation, concerning relations between central leadership and a tribal one, and when their decision-making process is similar to a confederate one. For example, even if at the beginning of its existence, the Hun tribal alliance resembled a confederate structure, under the rule of Attila the Hun, it cannot be considered a confederation , because the central authority – Attila as king – was the main decision maker. It is more appropriate to call these structures 'tribal alliances', as this term is more general and does not impose a certain kind of power structures.

Statehood and nationalism prevail even in those parts of the world where tribal identity is still strong. There are countries, however, in which a tribal alliance or confederate structures are very strong and determine internal politics. Such is the case in Yemen, where the Hashid, Bakil, and Madhaj tribal confederations are playing important roles in state politics.

Confederate Projects from the Prehistory of European Construction

The process of European Integration has deep roots within the thinking of European intellectuals, dating back for centuries. Most of the projects were designed as federation projects, with a few exceptions. This section describes those projects that envisaged a confederate structure.

One of the first coherent projects for unity of Christian Europe was elaborated by Pierre Dubois (1255–1321), a publicist and jurist who was in service of both Philip the Fair of France and Edward I (Longshank) of England. In his writings, especially in the *De recuperatione terrae sanctae*, he suggested the need for unity of all European Christian nations and monarchs for the success of the crusade against the Muslim world. He suggested the creation of a European confederation under the spiritual authority of the Papacy. The confederation was accompanied by monastic and military reforms, the constitutive states were preserving their sovereignty. The internal peace was granted by a court appointed by the Council of the Members of the Confederation, which could adopt

certain sanctions. As Ladislau Gyémánt wrote, "it was for the first time that such a project took into consideration the issue of the relationship between state sovereignty and supranational institutions – the core issue of the further debates on this topic" (Gyémánt, 1999).

Unlike Dubois, George Podiebrad (in his noble name George of Kunstat and Podiebrady; 1420–71) was a monarch, the king of Bohemia (1458–71). Because of his sympathy for the Hussites, he entered in conflict with Pius II. Conscious of the Ottoman threat, even though Bohemia shared no common border with the emerging Turkish empire, its southern neighbor, Hungary, did, and King Mathias of Hungary was the son-in-law of Podiebrad, and to improve his precarious position among European monarchs, King Mathia presented to King Louis XI of France and to the Republic of Venice a project of an anti–Ottoman European confederation. This project proposed the creation of a confederation of all of the states of Western Christianity, based on a treaty and lead by an assembly, residing in the first 5 years of its existence in Basel, and then changing its location on the basis of a rotation among different European cities. In the Assembly, one vote was granted for each of the sovereigns, with decisions being taken by majority of vote. Besides the coordinated anti-Ottoman efforts, the confederation was meant to grant the existing status quo by preventing war among its members, and with disputes being solved by a Court of Justice or general Consistory, which was appointed by the Assembly. Although Podiebrad's project was rejected, centuries later it inspired Herman Van Rompuy, president of the European Council, to say the following in Prague, on 25 April 2013: "One could think as far back as King Podiebrad, in fifteenth-century Bohemia, who launched an initiative for all European kings and princes to come together in a Council. In fact it was the first ever idea of the European Council!" (Van Rompuy, 2013).

Emeric Crucé (1590–1648), political thinker and one of the first pioneers for the theory of international relations and pacifist ideas, is the author of the first project including the known world of that time in a federal or confederate structure. In his work, Nouveau Cynée ou Discours d'Estat représentant les occasions et moyens d'establir une paix générale et la liberté de commerce pour tout le monde (1623), he projected the creation of an international structure including all of the European states, Russia, the Turkish empire, Persia, China, Japan, Ethiopia, the East and West Indies, Morocco, and the Tatars. The role of this new structure was to maintain permanent peace and to ensure freedom of commerce and development of economy and science. The main ruling body was meant to be a permanent Assembly or Senate of the member states, residing in Venice and presided by the Pope. Crucé's plan did not receive much publicity during his life and in the forthcoming centuries, and most of his ideas seems to be too idealist even for the twenty-first century. It also can be considered to be the early predecessor of the ideas on which the current largest international organization, the United Nations, is based.

Vincenzo Gioberti (1801–52), Italian philosopher, priest, and politician, was highly influenced in his intellectual formation by the religious education received in his youth and by the idealist revolutionary ideas of Giuseppe Mazzini. Gioberti contributed his Church-centered concepts to that time's debate on the future of Italy and the need for its unification. In his view, the unification of Italy was to be realized as a confederation of a series or sovereign regional states, under the authority of the Papacy. But this was meant to be only the first phase in Gioberti's mind, being followed by the unification of the whole Europe in similar terms, granting for each one of the European states and nationalities their own specificity. On the top of this system was meant to be the Pope, exercising the right of arbitration as a peaceful spiritual power.

Lajos Kossuth (1802–94), Hungarian lawyer and politician, was the most representative leader of the Hungarian Revolution and Freedom Fight from 1848 to 1849. He was author of the most coherent revolutionary plan from the period 1848–1914, which was meant to reorganize the state system of East-Central Europe. Following the defeat of the Hungarian Revolution by the Habsburg Monarchy using Tsarist support, Kossuth in emigration became a sworn enemy of the Habsburgs and was planning for the independence of the historical Hungarian kingdom in a nation-state form, which would maintain strict cooperation with its neighbors. As for the future of the entire region, Kossuth expressed his ideas in two successive works, in 1851 and in 1862. The basic ideas for both were the dismantle of the Habsburg empire and the reorganization of the region, using French or Italian backup, in a confederation of independent national states, with the respect of historical borders and tradition.

Postimperial and Postcolonial Transitory Confederate Structures

In the opinion of some scholars – among them the Hungarian professor emeritus Horváth Jenő – certain structures, like the commonwealth; the French Union as it appeared post–World War II with the dissolution process of the British and French colonial empires; or the Commonwealth of the Independent States, created after the fall of Communism by the great part of the states of the former Soviet Union (Horváth, 2005: pp. 30–31) were born because of a need for compromise. The compromise would grant the independence and national sovereignty for those states that had just obtained their independence, but it also would allow the former imperial center to maintain a part of its former influence, at least on a symbolic level. It also prevents violent splits, with disintegration of the structure taking place gradually. The structure is also an umbrella for new, territorially smaller, but more integrated structures like the Eurasian Economic Community.

The Confederation of Serbia and Montenegro

Serbia and Montenegro (2003–06) was a confederation, representing the final moment of the dissolution of the former federal state of Yugoslavia. The confederation had a common president (Svetozar Marovic) and limited competence in issues of defense and foreign affairs. The confederation met its end through the successive formal declarations of independence of its two components in 2006. The independence of Montenegro represented the last step of the dissolution of the federal Yugoslav Republic.

Notable Examples of Confederate Systems in Europe

The German Confederation (1815–66)

The German Confederation or the Deutscher Bund was the result of realistic great power politics of the Congress of Vienna, 1815. The main idea was the creation of a structure that could prevent any possible French future aggression and is in harmony with the principles of the Holly Alliance. The Napoleonic wars proved how vulnerable the divided German-speaking world could be in front of an external great power; however, at the same time, neither Austrian or Prussian hegemony was desired by others. As a consequence, the German Bund was created as a successor of the defunct Holy Roman Empire and of the Napoleonic structures of the Confederation of the Rhine. The peace of Paris (1814) established that the states of Germany should be independent, but also united in a federative structure. The Final Act of the Congress of Vienna (1815) established the constitutional environment of the Bund, which was completed by the Final Act of Vienna (1820). The Bund was meant to ensure internal security of peace of the German-speaking world and possible conflicts were meant to be brought in front of specialized commissions of the Confederate Assembly; if the mediation of the commission failed, the conflict would be submitted to a neutral court. Members of the Confederation had different ranks and rights in the Confederation, and non-German-speaking territories of German monarchs were not included in the Bund. The two chambers of the Congress, the Inner Council and the Plenum, adopted decisions in different ways. In the Plenum, each member had one vote, and in the Inner Council, important states had one vote each, whereas the smaller members – states having rulers that were not crowned heads – had collective voting rights. The Bund met its end with the Prussian victory against Austria in 1866 (Haldén, 2013).

The Swiss Confederation

Switzerland or the Swiss Confederation is an example of an integrated federal state that calls itself a confederation. It was constituted as a confederacy of three cantons from the Alps, as a consequence of common security politics, and with the expansion of the structure, it retained its original name. The confederacy facilitated common interests of its member cantons in common issues of security and defense, leaving a series of legal competence in the cantonal jurisdiction. Throughout history, these often lead to civil war, like the two Wars of Kappel in the sixteenth century or the Sonderbund War in 1847. Although Switzerland now functions as a federal democratic republic, it has retained its official name the Swiss Confederation (in Latin, *Confoederatio Helvetica*). From the point of view of constitutional evolution of Switzerland, three major periods are distinguished in history: the period of the Old Swiss Confederacy (1291–1798), the Napoleonic Era or the years of the Helvetic Republic (1798–1815), and the period of the federal state.

Other Examples

The United States of Belgium (1790) was a short-lived historical predecessor of modern Belgium in the form of a confederate republic of eight provinces from the Southern Netherlands, who rebelled against the rule of the Habsburg emperor Joseph II. The rebellion is known also as 'Brabantse revolutie' orthe 'Brabant revolution', and is one of the best historical examples of Flemish and Walloon coordinated efforts. During the short existence of this state, each one of the provinces had its own government, and the common government had its seat in Brussels, with representatives from all of the eight provinces. The revolt was defeated by the Habsburg Army of Leopold II, the successor of Joseph II, but it represented a model for the subsequent and more successful revolution of 1830, which created the modern state of Belgium. Currently, Belgium is a federal state that shares a few common aspects with a confederation.

Confederate Ireland (1642–49) was created by the special conjuncture of the English Civil War. Following the outbreak of hostilities between the King and the Parliament in England, the Irish Catholic elite remained loyal to the rule of Charles I. The initiative was formulated by the catholic bishop of Ferns, Nicholas French, and the Catholic Church played a major role in the confederation's politics. The central organs were the General Assembly, as legislature, and the Supreme Council, as executive, while the head of state was accepted to be the king of Britain. The Irish Catholic Confederation met its end by the invasion of the English Parliamentary Army led by Oliver Cromwell in 1649.

The European Union has no common classification, and the current structure resembles in some aspects a federation, in others, a confederation. The European Union operates common economic policies and has several common institutions, but its leadership lacks efficient centralization, and its competences in fields like issues of foreign policy and defense, despite all the efforts, are seriously limited. Member states of the European Union are preserving, in great part, their sovereignty.

Confederate Structures of North America

Native American Confederacies of North America

Native Americans had several confederate structures, perhaps the most well known is the Iroquois Confederation, a structure that currently is functioning. It is based on the Great Binding Law, an orally transmitted Constitution. The primary purpose of this confederate structure was to maintain peace among its members. Inequality of its members was institutionalized in the decision-making process. Originally, the confederation had 'five nations', with the Tuscarora becoming the sixth nation in 1722. The common institution for debates was the Confederation Council, which was hosted on the Onondaga territory and had 50 sachems, delegated by the participants. Originally, the Onondaga had 14 sachems, the Cayuga had 10, the Mohawk and Oneida had nine each, and the Seneca had eight. When the Tuscarora joined, they received six sachems, and total membership of the Council was increased to 56. The decision-making process required, at its end, unanimity. When a decision that implied the competence of the whole confederacy was meant to be taken, deliberations were held by each tribe following an established order. The first ones who deliberated the issue were the Mohawks; after they reached a decision, their

proposal was conveyed to the Seneca, and then to the Oneida and to the Cayuga, with the Onondaga being the last (Lutz, 1998). Because of its efficiency, the Confederation earned the respect of other Native American tribes and also of the colonists coming from Europe. The confederacy lost its real power following to the American War of Independence, but a common organization of the Iroquois still exists and sometimes acts as an independent actor of International Relations.

Confederate Experience of the United States of America

In the first phase of the existence of the independent United States of America was in form of a confederation. Its functioning was based on the Articles of Confederation, which first served as a provisional Constitution of the States, starting in 1777. It was replaced by the current US Constitution in 1789. The confederation included independent and sovereign states, which were preoccupied in protecting their freshly won freedom against active and possible threats.

A second phase of the American confederate experience took place in 1860–65, when political and social internal tensions caused the secession of several southern states of the Union. The Confederate States of America was a structure created in 1861 by several member states of the United States of America, as a consequence of their secession from the Union following the election as president of Abraham Lincoln. The United States rejected the secession and considered the confederacy to be illegal and defeated it in a bloody civil war (1861–65), which forced the secessionists to return in the Union. Originally, seven southern states declared their secession and later were joined by another four states following to the outbreak of the Civil War.

The first capital of the Confederacy was Montgomery, in the state of Alabama, from 4 February until 29 May 1861. The capital later moved to Richmond. Its first and only president was Jefferson Davis (1861–65) seconded by Alexander Stevens as vice president, and with the legislative power being represented by a bicameral legislature. The legislation of the confederacy was based on the Confederate States Constitution, which replicated in great part the US Constitution, with a few major differences.

Experience in Canada

Is one of the world's oldest liberal federations, an efficient solution was to keep together in one single unit Catholics and Protestants, French and English speakers, Native Americans and European colonists. The federation was born by a certain conjuncture: The British Crown held its control over these territories, but it was seriously threatened by their southern neighbor, the United States.

The 1867 confederation was designed under the auspice of equal rights of the two major communities. In fact, Canada is a federation and not a confederation. It was constituted in 1867 under the use of this term, as a self-governing Dominion of the British Empire. It consists of provinces and territories, with each one having extended competences in most major aspects of public administration and social life.

Canada has retained its bilingual character, somehow as a compensation for the French Canadians, whose existence within the state provided a cultural impediment on US expansion and a possible forced merging of Canada with the United States.

Tribal Confederacies of Pre-Columbian Mexico

The Chalco Altapetl or confederacy was a tribal alliance of the Chalca people in pre-Columbian Mexico, rivaling the more famous Aztec Empire, with which they waged wars for centuries. When Hernando Cortes landed in Mexico, Chalco was submitted to the Aztecs and paid tribute to them, but it quickly allied itself with the conquistadors and contributed in the defeat of Tenochtitlan. After the fall of the Aztecs, the Chalco accepted Spanish rule without major opposition.

The Aztec Empire was functioning as a confederation of city-states sharing common cultural heritage. Initially, it was created as an alliance of the states of Tenochtitlan, Acolhuacan (known after its capital more as Texcoco), and Tlacopan, coordinating common foreign policy and wars, with each one of them keeping its sovereignty in domestic affairs. With time, Tenochtitlan became the effective leader and the most representative state of the alliance; however, the other two allies kept their competencies and certain responsibilities divided. For example, Acolhuacan had most of its competencies in legislation and construction of public buildings, the elite of Tlacopan was responsible for the economy and handicraft, and Tenochtitlan kept the role of the most important religious center and was responsible for war and common foreign policy (Kulmar, 2010). As a result of its successful wars, the Triple Alliance formed an empire with a series of subsidiary provinces paying tribute to the Aztecs. The Aztec Empire was conquered by the Spaniards lead by Cortes in 1521.

Confederate Ideas and Structures in Latin America, Asia, and Africa

Confederate Experience in Postcolonial Latin America

The Argentine Confederation is one of the official names of Argentina, according to its Constitution. From 1831 to 1852, Argentina could be called an effective confederation when the provinces organized themselves without having a common president. Similar confederate structures in postcolonial Latin America included the Peru–Bolivian Confederation (1836–39) and the Granadine Confederation (1858–63).

Confederate Structures in Asia and the Far East

For most of Europeans, the great civilizations of the Far East are characterized by magnificent ancient culture, fatalist religions, and well-functioning, centralized states. In certain periods of their existence, however, certain cultures had confederate structures, special conjunctures, and a certain amount of historical time. These civilization can be included in the category of 'notable exception' rather than into a general trend, and even if some had lasted for centuries, they had a transitory character, because they were the result of a series of circumstances and not of an expressed need of the society.

During the history of the Korean peninsula, in the Proto-Three Kingdoms period, several independent tribes and

states created confederations. Such confederations were Mahan, Byeonhan, and Jinhan, which developed into the three kingdoms. A subsequent confederacy was the Gaya confederacy, which developed from the Byeonhan and led to a five-centuries-long independence, but was annexed to the kingdom of Silla.

The Confederation of the Madja, a state in the Philippines, was established by Bornean rebels who were forced by the monarch to leave the country. The new state was established in the Visayas Islands and was considered to be very efficient in wars. It fell under Spanish control in a series of successive colonizing actions between 1565 and 1716.

The Maratha Empire from North India was functioning as an aristocratic confederation in the last stage of its existence, starting with the death of Madhavrao I (1772) and ending with its conquest by the British Empire (1818). During this period, the common monarch, the Peshwa, had limited powers, and the Empire's politics were determined by the cooperation and rivalry between its subsidiary local dynasties.

African Confederate Experiences

Sub-Saharan Africa was and still is the home to several tribal confederacies. Some notable structures in African history include the Aro Confederacy (1690–1902) in the southern territories of modern-day Nigeria, with its center in the Arochukwu Kingdom. The confederacy united several city-states and kingdoms, and the binder of the confederacy was represented by a common economic interest of trading palm oil and slaves. The confederacy was destroyed by British conquest in 1902.

The Fante Confederacy and the Ashanti Confederacy are historical tribal confederations in Africa, from among which the Ashanti monarchy still exists in Ghana as a subnation-state. Generally, central institutions of postcolonial African states – where presidents, measured with European standards, often exercised dictatorial powers – are more comfortable accepting the existence and limited sovereignty of traditional tribal power structures than fighting against illegitimate warlords. As a consequence, centralization in a way that would abolish traditional tribal kingdoms and alliances is not very likely to happen in any state of Sub-Saharan Africa.

Pan-Africanism and Postcolonial Confederate Experiences of African States

George B.N. Ayittey, Ghanaian economist and supporter of Pan-Africanism, wrote the following: a "[m]odel would be an African Confederation, with extensive devolution of power to reflect Africa's own heritage: the ancient empires of Ghana, Mali Songhai and Great Zimbabwe were all confederacies, and they lasted centuries" (Ayittey, 2010). Although this sounds like an exaggeration, the pan-African movement is a serious debate among African intellectuals.

Pan-Africanism was developed over the late-ninetieth and early twentieth centuries to enhance emancipation of Black people of the colonies. Its founding belief is that people of Africa, regardless of their tribe, are sharing common problems and objectives. The ideology of Pan-Africanism and unification in an international cooperation of the continent was formed through a series of congresses between 1900 and 1927. During the decades of decolonization, the Organization of African Unity (OAU), in 1963, tried to promote idealistic ideals of democracy. This proved to stay only on a declarative, and as a consequence, the organization quickly lost its credibility because it lacked real power to improve the lives of Africans and to limit excesses of presidents and warlords. In 2001, the successor organization of the African Union was created in Libya.

In addition to the inefficient international organizations meant to enhance integration, two regional confederate attempts are worth mentioning. The Union of African States (or the Ghana-Guinea-Mali Union) was a regional organization formed from 1958 to 1963 in postcolonial Western Africa. It was based on the friendship of the three presidents, Kwame Nkrumah of Ghana (1958–66), Ahmed Sekou Toure of Guinea (1958–84), and Modibo Keita of Mali (1960–68). The charter of the Union was adopted in 1961, containing mutual assistance in case of war and cooperation in the plan of economic and cultural activities. The three leaders expressed high ambitions concerning integration processes, such as a common parliament, common flag, unification of diplomacy and economic policies, and so on. Most of these objectives proved to be unrealistic at that time, and the cooperation never passed through the level of occasional summits of the three presidents.

Senegambia (1982–89) was a confederation between the states of Senegal and Gambia, born because of common issues of internal security. During its existence, the integration process never went further than the military assistance of Senegalese Army against Gambian leftist rebels. After Gambia resisted with success to Senegalese pressure to move closer toward a union, Senegal dissolved the confederation in 1989.

In Africa, there is expressed need for regional or continental integration processes, and responsible politicians and intellectuals are clearly calling for this integration. Until most of the African states are wrestling with serious internal problems, however, the successful completion of an integration process, similar to the European one, is less likely.

State Confederations in the Arab World during the Cold War

From 1958 to 1961, the United Arab States was a confederation of Egypt, Syria, and North Yemen. This confederation was realized in two steps. First, the United Arab Republic (UAR) was formed by the union of Egypt and Syria in 1958, under the leadership of president Gamal Abdel Nasser. The structure was dominated by the Egyptian leading elite, which caused dissatisfaction in Syria, and ultimately led to its secession in 1961. From the region, Israel, Saudi Arabia, and Jordan were the most fervent opponents of the UAR.

In 1958, North Yemen, which previously signed a defense treaty with Nasser's Egypt, joined the UAR in a loose confederation. Unlike Syria, North Yemen remained an independent sovereign state under the rule of its own king, and was acting as an independent actor in global politics. The United Arab States was dissolved in 1961.

The Arab Federation of Iraq and Jordan was a confederate structure formed by the Hashemite kingdoms of Iraq and Jordan, and lasted from 14 February until 2 August 1958. The two kings, Faisal II of Iraq and Hussein, were cousins, and they

formed this union as a reaction to the rising of the menace represented by the ambitions of the Egyptian president Nasser. The Arab Union united the foreign policy and defense functions of the two countries, leaving the rest of the issues under national jurisdiction. Both of the kings kept their thrones, and Nuri as-Said was named as prime minister of the Union. The end of the Union was brought by a military coup in Baghdad, which resulted in the fall and death of King Faisal II.

Confidentiality and Statistical Disclosure Limitations

Abstract

Under confidentiality, identifiable data provided for statistical purposes is protected from unauthorized disclosure. Organizations acting as brokers between respondents and data users seek to disseminate useful data products while keeping low the risk of confidentiality disclosure. Recognizing that deidentification of each data record is generally inadequate to protect its confidentiality against attack by a data snooper, agencies restrict the data they release for general use. Typically, these restricted data procedures have involved transformation or masking of the original, collected data through such devices as adding noise, topcoding, data swapping, and recoding. Another approach is to use the original data to determine a statistical model and use it to generate synthetic data. Generically, statistical disclosure limitation is a body of restricted data procedure that transforms data so that release of the transformed data adequately limits disclosure risk. Desirably, statistical analysis of the transformed data leads to inferences similar to that obtained by analysis of the original data. The technical procedures for implementation of disclosure limitation involve a range of mathematical and statistical tools.

Data Quality Rests on Usefulness and Confidentiality Protection

We capture enormous numbers of rich personal and proprietary records, store them in data warehouses measured in terabytes, analyze them using sophisticated computers and algorithms, and disseminate them worldwide via telecommunications channels that are cheap and fast. This explosive progress in information technology – look at the World Wide Web – heightens the tension between confidentiality and data access. Accepted principles of information ethics (Duncan et al., 1993) require that promises of confidentiality be preserved and that citizens have substantial access to information. Policies and procedures are needed to reconcile the data provider's interest in confidentiality and the data user's demand for data (Dalenius, 1988). Government statistical agencies, such as the US Census Bureau, play a particularly significant and delicate brokering role in this reconciliation of competing demands. They often have legal authority to compel individuals and firms to provide data, and the data are both sensitive – like personal income – and so comprehensive and accurate to be in substantial demand by a broad range of data users. Academic researchers, corporate planners, journalists, and government analysts all seek such data. Other organizations, such as health care providers, necessarily collect data in treating patients that is highly personal. These data are of substantial research value for issues spanning medical quality assurance, cost containment, and access to medical treatment by the poor (Duncan and Kaufman, 1996).

A compromise of the confidentiality pledge could harm the agency, the respondent, the public, or some other group. A statistical disclosure occurs when the data dissemination allows data snoopers to gain excessive new information about respondents whereby the snooper can isolate individual respondents and corresponding sensitive attribute values. Miller (1971: 176) illustrates the problem.

> Some deficiencies inevitably crop up even in the Census Bureau. In 1963, for example, it reportedly provided the American Medical Association with a statistical list of one hundred and eighty-eight doctors living in Illinois. The list was broken down into more than two dozen categories, and each category was further subdivided by medical specialty and area residence; as a result, identification of individual doctors was possible…

As shown in Figure 1, the process of assuring confidentiality through statistical disclosure limitation has the following components:

1. a data quality audit that, beginning with the original collected data, evaluates data utility and assesses disclosure risk;
2. a determination of adequacy of confidentiality protection;
3. if confidentiality protection is inadequate, the implementation of a disclosure limitation procedure; and
4. a return to the data quality audit.

Data Quality Audit: Data Utility and Disclosure Risk

A statistical agency audits the collected data, both to evaluate the utility of the data and to assess disclosure risk. Typically, with good survey design and implementation, the data utility is high. But, also, the risk of disclosure through the release of the original, collected data is too high, even when the data collected have been deidentified, i.e., apparent identifiers (name, e-mail address, phone number, etc.) have been removed. Reidentification techniques have become too sophisticated to assure confidentiality protection (Winkler, 1998). A confidentiality audit will include identification of

Figure 1 Statistical disclosure limitation process.

(1) sensitive objects and (2) characteristics of the data that make it susceptible to attack.

Based on its confidentiality pledges, a statistical agency seeks to protect certain sensitive objects. An agency seeks to protect the instantiation of sensitive objects in the data from a data snooper. Sensitive objects can be the instantiations of a variety of variables associated with a subject entity (person, household, enterprise, etc.). Examples include the values of numerical variables, such as household income, a realization of an x-ray of a patient's lung, and a specific patent application. A second class of sensitive objects is instances of relationships, whether social or mathematical. An example of the former is 'Who is friends with whom?' in a social network; an example of the latter is an Internal Revenue Service formula to trigger a tax audit.

Collected data having particular characteristics pose substantial risk of disclosure. Characteristics that suggest vulnerability include:

1. geographical detail (Greenberg and Zayatz, 1992);
2. longitudinal or panel structure;
3. outliers;
4. many attribute variables;
5. population data, as in a census, rather than a survey with small sampling fraction; and
6. existence of databases that are publicly available, identified, and share individual respondents and attribute variables with the subject data.

Data with geographical detail, such as census tract data, may be easily linked to known characteristics of respondents. Concern for this leads statistical agencies to place minimum population levels for geographical identifiers that they will release. Longitudinal data, which tracks entities over time, also poses substantial disclosure risk. Many electrical engineers lived in the Chicago area in 1998 and many electrical engineers lived in the Phoenix area in 1999, but few did both. Outliers, especially on variables like net worth, can easily lead to identifiable respondents. Data with many attribute variables allows easier linkage with known attributes of identified entities, and entities, which are unique in the sample, are more likely to be unique in the population. Further, population data, i.e., a census or near census, pose more disclosure risk than data that arise from a survey having a small sampling fraction. Finally, special concern must be shown when other databases are available to the data snooper and these databases are both identified and share with the subject data both individual respondents and certain attribute variables. Record linkage may then be possible between the subject data and the external database. The shared attribute variables provide the key.

Types of Statistical Disclosure

The legitimate objects of inquiry for statistical research are aggregates over individual records, for example, the median annual income of Hispanic social scientists in the United States. The statistical agency seeks to provide users with data that will allow accurate inference about such population characteristics. At the same time, because of confidentiality the statistical agency seeks to thwart the data snooper who might seek to use the disseminated data to draw accurate inferences about, say, the income of a particular Hispanic sociologist who now works in New York City. This capability by a data snooper represents a statistical disclosure.

There are two major types of disclosure – identity disclosure and attribute disclosure. *Identity disclosure* occurs with the association of a respondent's identity and a disseminated data record (Spruill, 1983). *Attribute disclosure* occurs with the association of either an attribute value in the disseminated data or an estimated attribute value based on the disseminated data with the respondent (Duncan and Lambert 1989; Lambert, 1993). In the case of identity disclosure, the association is assumed exact. In the case of attribute disclosure, the association can be approximate. Most statistical agencies place emphasis on limiting the risk of identity disclosure, perhaps because of its substantial equivalence to the inadvertent release of an identified record – a clear administrative slip up. On the other hand, an attribute disclosure, even though it invades the privacy of a respondent, may not be so easily traceable to actions of the agency.

Measures of Disclosure Risk

In the context of identity disclosure, disclosure risk can arise because a data snooper may be able to use the disseminated data product to re-identify some deidentified records. Spruill (1983) proposed a measure of disclosure risk for microdata: For each 'test' record in the masked file, compute the Euclidean distance between the test record and each record in the source file. Determine the percentage of test records that are closer to their parent source record than to any other source record. She defines the risk of disclosure to be the percentage of test records

that match the correct parent record multiplied by the sampling fraction (fraction of source records released).

More generally, and consistent with Duncan and Lambert (1986, 1989), the agency will have succeeded in protecting the confidentiality of a released data product if the data snooper remains sufficiently uncertain about a protected target value after data release. From this perspective, a measure of disclosure risk is built on measures of uncertainty. Further, the agency may model the decision making of the data snooper as a basis for using disclosure limitation to deter inferences about a target. Data snoopers are deterred from publicly making inferences about a target when their uncertainty is sufficiently high. Mathematically, uncertainty functions provide a workable framework for this analysis. Examples include Shannon entropy, which has found use in categorizing continuous microdata and coarsening of categorical data (Willenborg and de Waal, 1996: 138).

Generally, a data snooper has *a priori* knowledge about a target, often in the form of a database with identified records (Adam and Wortmann, 1989). Certain variables may be in common with the subject database. These variables are called *key* or *identifying*. When a single record matches on the key variables, the data snooper has a candidate record for identification. This candidacy is promoted to an actual identification if the data snooper is convinced that the individual is in the target database. This would be the case either if the data snooper has auxiliary information to that effect or if the data snooper is convinced that the individual is unique in the population. The data snooper may find that according to certain key variables that a sample record is unique. The question then is whether the individual is also unique on these key variables in the population. Bethlehem et al. (1990) have examined detection of records agreeing on simple combinations of keys based on discrete variables in the files. Record linkage methodologies have been examined by Fuller (1993) and Winkler (1998).

Restricted Data through Statistical Disclosure Limitation

Direct transformations of data for confidentiality purposes are called *disclosure limiting masks* (Jabine, 1993). With masked data sets, there is a specific functional relationship, possibly as a function of multiple records and possibly as a stochastic function, between masked values and the original data. Because of this relationship, the possibilities of both identity and attribute disclosures continue to exist, even though the risk of disclosure may be substantially reduced. The idea is to provide a response that, while useful for statistical analysis purposes, has sufficiently low disclosure risk. As a general classification, disclosure-limiting masks can be categorized as suppressions, recodings, or samplings.

Suppression

A suppression is a refusal to provide a data instance. For microdata, this can involve the deletion of all values of some particularly sensitive variable. In principle, certain record values could also be suppressed, but this is usually handled through recoding. For tabular data, the values of table cells that pose confidentiality problems are suppressed. These are the primary suppressions. Often, a cell is considered unsafe for publication according to the (n, p) dominance rule, i.e., if a few (n), say 3, contributing entities represent a percentage p, say 70%, or more of the total. Additionally, enough other cells are suppressed so that the values of the primary suppressions cannot be inferred from released table margins. These additional cells are called secondary suppressions. Tables of realistic dimensionality even with only a few primary suppressions present a multitude of possible configurations for the secondary cell suppressions. This raises computational difficulties that can be formulated as combinatorial optimization problems. Typical techniques that are employed include mathematical programming (especially integer programming), and graph theory (Chowdhury et al., 1999).

Recoding

A disclosure-limiting mask for recoding creates a set of data for which some or all of the attribute values have been altered. Recoding can be applied to microdata or to tabular data.

Examples of recoding as applied to microdata include data swapping, adding noise, and global recoding and local suppression. In data swapping (Dalenius and Reiss, 1982; Spruill, 1983), some fields of a record are swapped with the corresponding fields in another record. Concerns have been raised that while data swapping lowers disclosure risk it may excessively distort the statistical structure of the original data (Adam and Wortmann, 1989). A combination of data swapping with additive noise has been suggested by Fuller (1993). Masking through the introduction of additive or multiplicative noise has been investigated (e.g., Fuller, 1993). A disclosure limitation method for microdata that is used in the μ-Argus software is a combination of global recoding and local suppression. Global recoding combines several categories of a variable to form less-specific categories. Topcoding is a specific example of global recoding. Local suppression suppresses certain values of individual variables (Willenborg and de Waal, 1996). The aim is to reduce the set of records where only a few agree on particular combinations of key values. Both methods make the data less specific and so result in some information loss to the legitimate researcher.

Some common methods of recoding for tabular data are global recoding and rounding. Under global recoding, categories are combined. This represents a coarsening of the data through combining rows or combining columns of the table. Under rounding, every cell entry is rounded to some base b. The controlled rounding problem is to find some perturbation of the original entries that will satisfy (marginal, typically) constraints and that is 'close' to the original entries (Cox, 1987). Multidimensional tables present special difficulties. Methods for dealing with them are given by Kelley et al. (1990).

Markov perturbation (Duncan and Fienberg, 1999) makes use of stochastic perturbation through entity moves according to a Markov chain. Because of the cross-classified constraints imposed by the fixing of marginal totals, moves must be *coupled*. This coupling is consistent with a Gröbner basis

structure (Fienberg et al., 1998). In a graphical representation, it is consistent with data flows corresponding to an *alternating cycle*, as discussed by Cox (1987).

Sampling

Sampling as a disclosure-limiting mask creates an appropriate statistical sample of the original data. Alternatively, if the original data is itself a sample, the data may be considered self-masked. Just the fact that the data are a sample may not result in disclosure risk sufficiently low to permit data dissemination. In that case, subsampling may be required to obtain a data product with adequately low disclosure risk.

Whether for microdata or tabular data, many of these transformations can be represented as matrix masks (Duncan and Pearson, 1991), $\mathbf{M} = \mathbf{AXB} + \mathbf{C}$, where $\mathbf{X}$ is a data matrix, say $n \times p$. In general, the defining matrices $\mathbf{A}$, $\mathbf{B}$, and $\mathbf{C}$ can both depend on the values of $\mathbf{X}$ and be stochastic. The matrix $\mathbf{A}$ (since it operates on the rows of $\mathbf{X}$ is a record-transforming mask), the matrix $\mathbf{B}$ (since it operates on the columns of $\mathbf{X}$ is a variable-transforming mask), and the matrix $\mathbf{C}$ is a displacing mask (noise addition).

Synthetic or Model-Based Data

The methods described so far have involved perturbations or masking of the original data. These are called *data-conditioned* methods by Duncan and Fienberg (1999). Another approach, while, less studied, should be conceptually familiar to statisticians. Consider the original data to be a realization according to some statistical model. Replace the original data with samples (the synthetic data) according to the model. Synthetic data sets consist of records of individual synthetic units rather than records the agency holds for actual units. Rubin (1993) suggested synthetic data construction through a multiple imputation method. It remains an open research question as to what the impact of imputation of an entire microdata set is on data utility.

Rubin (1993) asserts that the risk of identity disclosure can be eliminated through the dissemination of synthetic data and proposes the release of synthetic microdata sets for public use. His reasoning is that the synthetic data carries no direct functional link between the original data and the disseminated data. So while there can be substantial identity disclosure risk with (inadequately) masked data, identity disclosure is, in a strict sense, impossible with the release of synthetic data. However, the release of synthetic data may still involve risk of attribute disclosure (Fienberg et al., 1998).

Rubin (1993) cogently argues that the release of synthetic data has advantages over other data dissemination strategies, because

1. masked data can require special software for its proper analysis for each combination of *analysis* × *masking method* × *database type* (Fuller, 1993);
2. release of aggregates, e.g., summary statistics or tables, is inadequate due of the difficulty in contemplating at the data-release stage what analysts might like to do with the data; and
3. mechanisms for the release of microdata under restricted access conditions, e.g., user-specific administrative controls, can never fully satisfy the demands for publicly available microdata.

The methodology for the release of synthetic data is simple in concept, but complex in implementation. Conceptually, the agency would use the original data to determine a model to generate the synthetic data. But the purpose of this model is not the usual prediction, control, or scientific understanding that argues for parsimony through Occam's Razor. Instead, its purpose is to generate synthetic data useful to a wide range of users. The agency must recognize uncertainty in both model form and the values of model parameters. This argues for the relevance of hierarchical and mixture models to generate the synthetic data.

Summary

A society based on democratic and free market principles cannot function without broad access to data, nor can it sustain those principles without affirming the individual autonomy assured by privacy and confidentiality. Statistical disclosure limitation methods work to ensure that the tension between data access and confidentiality can be resolved in ways that are favorable to both. This methodology draws on disparate fields of mathematics and is challenged to develop in response to the growing capability of information technology to capture, store and disseminate data. To learn more about this topic, see *Private Lives and Public Policies: Confidentiality and Accessibility of Government Statistics* (Duncan et al., 1993), two special issues of the *Journal of Official Statistics* (Jabine, 1993 and Fienberg et al., 1998), the Federal Committee on Statistical Methodology, 1994 and Duncan and Fienberg (1999).

This article is a revision of the previous edition article by D.G. Pruitt, volume 4, pp. 2531–2534, © 2001, Elsevier Ltd.

Abstract

Social psychology has made important contributions to the study of social conflict and to methods for the resolution of conflict between parties, particularly at the intergroup level. This article outlines perceptual and cognitive processes along with group and intergroup dynamics that feed conflict escalation and intractability. While augmenting the study of negotiation and mediation, social psychology has led the development of interactive conflict resolution, which engages members of conflicting parties in analysis, dialogue, and problem solving.

Introduction

Social psychology is both a subfield of sociology and psychology, and as an 'interdiscipline' is concerned with how the behavior of individuals is influenced by and in turn influences others in various social contexts. It focuses on how individual motives, attitudes, and actions are intertwined with those of others in social relationships and interactions, such as social conflict. Conflict can be defined as "a social situation involving perceived incompatibilities in goals or values between two or more parties, attempts by the parties to control each other, and antagonistic feelings by the parties toward each other" (Fisher, 1990: 6). Social conflict thus has three main components: differences between individuals or groups, attempts to influence each other, and negative feelings that develop along with this interaction. Conflict resolution is seen as the management of differences in a manner that is constructive and cooperative, and yields outcomes that are mutually satisfactory and have a long-term commitment from the parties. Thus, conflict analysis and resolution is compatible with the nature of social psychology, and therefore, as this new multidisciplinary field of endeavor developed in the social and behavioral sciences, social psychologists were at the forefront, for example, in founding the *Journal of Conflict Resolution* in 1957 at the University of Michigan.

The social-psychological approach to conflict analysis and resolution is rooted in three key elements (Fisher, 1990). The first draws on the phenomenological nature of the discipline itself, which emphasizes the importance of subjective experience in determining human beings' representations of reality and our responses to it. Hence, perceptions, attitudes, and values held by individuals and shared by groups in conflict are an important determinant of their behavior in relation to the conflict and the other party. This element also holds promise for conflict resolution, in that cognitions can change and the valuing of different positions and outcomes is malleable. The second element emphasizes the critical role of behavioral interaction among the parties in terms of how they orientate, communicate, respond, and negotiate with each other over their differences. Conflict interaction is an emergent phenomenon, and how the parties treat each other is equally important as the nature of their interaction in determining the course and the outcomes of the conflict. The third element assumes that social conflict can only be understood by giving attention to multiple levels of analysis through a systems approach. The level of the conflict itself, whether it be interpersonal, intergroup, or international needs to be identified, and each of the levels involved needs to be analyzed for its contribution to the conflict interaction. For example, individual perceptions and cognitions are fundamentally important, but in intergroup conflict these need to be understood in the context of the group and intergroup environments in which they arise and operate. This is because members of groups do not operate freely as individuals, but in terms of their group identity and norms, and in response to past interactions between the groups. Social behavior in conflicts is thus multiply determined, and a wide range of variables at multiple levels must be considered in analyzing causation and in approaching resolution.

In addressing social conflict, this treatment does not assume that the phenomenon is predominantly good or bad for humankind – it is simply real and omnipresent. How situations of difference are approached and managed by the parties will determine whether the process and outcomes are constructive or destructive, or a combination of these two. Social conflict has a functional side in that it is often a source of social change toward greater justice and equality, among individuals, groups, and societies. If parties enter into conflict with open, complex communication, a cooperative orientation, a degree of flexibility in preferences with firmness on basic requirements, and sense that the conflict is a shared problem, then the probability of constructive processes and outcomes is increased. If parties enter the zone of the conflict with closed, manipulative communication, a competitive orientation, rigidity in perceptions and positions, and a sense that the conflict is a war to be won, then the norm of reciprocity determines that destructive escalation will occur to a point of mutual debilitation. Of course, parties often approach conflict in the latter manner with the confidence that their influence strategies will prevail, and they will win at reasonable cost and attain their desired outcomes. Unfortunately, the world is replete with instances where this has not occurred and parties become locked in intractable situations that demonstrate the clear need for the field of conflict analysis and resolution.

This article will outline most of the major contributions that social psychology has made to conflict analysis and resolution. It will begin by describing some of the perceptual and cognitive

factors, particularly distortions and biases, which can occur in conflict interaction and escalation, followed by some of the group-level dynamics, which tend to exacerbate the prosecution of the conflict. After identifying the common methods used to address conflicts, greater consideration will be given to interactive small group methods, primarily problem-solving workshops, which flow from a social-psychological analysis and principles.

Conflict Analysis

This section describes many of the conceptual contributions that social psychology has made to the understanding of social conflict (Bar-Tal, 2011; Fisher, 1990; Pruitt and Kim, 2004). The assumption is that one must first understand a social phenomenon in order to develop methods to address it, in this case, to manage conflict in a way that minimizes its destructive potential, especially the use of violence.

Social Perception and Cognition

Social psychology is in large part the study of how people see the world and how they think about it, because these processes in large part determine how they respond to it. Social psychologists have invested considerable effort in the study of attitudes, that is, an individual's tendency to evaluate and respond to social objects in a consistently favorable or unfavorable way. Attitudes are typically seen as composed of three components: a cognitive one consisting of the beliefs about the object, an affective one comprising the emotions connected with the object, and a behavioral one, which includes the action tendencies or orientations toward the object. In the study of social conflict, the cognitive component has predominated, particularly through the concept of stereotype, which is a simplified and rigid set of beliefs, usually negative, that are attached to a disliked or enemy group. Stereotypes are common in intergroup relations, and at a low level of hostility can be somewhat innocuous misperceptions of out-group attributes, while at the same time capturing some distinctive out-group characteristics. However, at higher levels of conflict intensity, stereotypes become exaggerated and inflexible, can result in selective and distorted perceptions, and can be used to justify destructive behaviors ranging from discrimination to dehumanization and to genocide.

The concept of image, popular in the study of international relations, builds on the idea of stereotypes, and is also congruent with the definition of attitude given above. Enemy images are very similar to negative stereotypes and see the other party in conflict as having undesirable characteristics (untrustworthy, irrational), deserving of hostile emotions (suspicion, hatred), and requiring coercive behavioral responses (deterrence, punishment). An additive concept is that of mirror image, in which each party in conflict holds a negative enemy image toward the other along with a positive image of itself, a cognitive construction which is of course impossible in reality. Thus, one's own group or country is regarded as good, peaceful, and well-intentioned, while the other side is seen as evil, aggressive, and malevolent, much like the modal perceptions held in the United States and the Soviet Union during the Cold War. The danger with such mirror images is not only that they influence ongoing perceptions in the direction of selectivity and distortion, but also that they drive escalation of the conflict to more intense levels, because countering actions by the other are interpreted as due to hostile and aggressive (rather than defensive) intentions and indeed to the very nature of the enemy as being malevolent, if not evil.

Causal Attribution

Social psychology studies the process of causal attribution by which individuals make judgments about the reasons for their own and other people's behavior, and about how they then make inferences about the characteristics of others, which of course affects how they may respond. A basic distinction is made on whether behaviors are attributed to the personal or dispositional characteristics of others and the group to which they belong, or to the situation or environment in which they are operating. This relates to the first common error relevant to social conflict, the so-called fundamental attribution error, by which observers of others' actions have a tendency to attribute causation to the inherent characteristics of the other, rather than to the situation. In contrast, individuals tend to attribute their own behavior to situational or contextual factors. Thus, in a social conflict, there is a bias for actors to attribute the other's behavior to their personality or culture, while seeing their own behavior more as responses to situational cues, including the other's actions.

At the level of intergroup relations, this bias feeds into the so-called ultimate attribution error, in which undesirable behaviors by an out-group member are more likely to be attributed to the negative characteristics of the out-group (and the individual group member) in line with the attendant stereotype. However, positive behaviors by an out-group member tend to be attributed to situational determinants, that is, rationalized and explained away. In contrast, desirable actions by an in-group member are seen as due to the positive in-group (and member) characteristics, captured in a self-serving in-group stereotype, while undesirable behavior is attributed to situational factors. In essence, out-group members cannot win in terms of attributions made, while in-group members cannot lose. Although these errors in attribution may not be universal, they likely feed conflict escalation and also may become more extreme as intensity and hostility between the groups moves to higher levels.

Confirmatory Mechanisms

Attribution processes in situations of intergroup conflict thus operate to confirm and strengthen group stereotypes, but they are not the only mechanisms that operate in this direction. In general, attitudes and images once formed tend to be resistant to modification, even in the light of contradictory experiences. Attitudes perform some important functions for individuals, including bolstering one's self-esteem, expressing one's values, and maximizing the benefits one receives from social behavior. However, once formed they can be blinders that restrict perceptions of social reality through selectivity and distortion of incoming information as well as the recall of received information. In all cases, information that is congruent with

existing cognitive structures, including attitudes, self-concept, and group identity, is more likely to survive and even thrive in how people see, interpret, and remember the social world.

One powerful confirmatory mechanism is the self-fulfilling prophecy in which the expectations defined by stereotypes can lead the holder of the stereotype to treat the object of the stereotype in ways that lead the object to then behave in ways that confirm the stereotype. This effect was first studied in the classroom, where teachers' expectations about the capabilities of their students (some of which were bogus ones incorrectly supplied to them) were found to be related to subsequent student performance, ostensibly because the teachers treated the students in line with their expectations. In social interaction in a context of intergroup conflict, this effect can be brought forward by stereotyped expectancies that one group holds of another group. For example, if an out-group is perceived as untrustworthy, members of that group will likely be treated with caution and suspicion, which may signal them to behave in nontrusting and noncooperative ways, thus confirming the original expectation.

A powerful force in the confirmatory power of existing attitudes and images is found in the concept of cognitive dissonance, which is an unpleasant psychological tension created by inconsistency between different cognitive elements, such as between our attitude and the attitudes of important others, or between our beliefs and our actions. Individuals can attempt to reduce the inconsistency and the dissonance through a variety of actions, such as changing their beliefs or behavior, or seeking more information to support their existing beliefs, or explaining away the contradictory information. With strongly held beliefs, such as negative stereotypes, it is more likely that the individual will work to maintain consistency by screening out or reinterpreting contradictory information or experiences, thus maintaining consistency and preserving the stereotype.

Social Judgment and Decision-Making

The numerous biases and errors in gathering, interpreting, and recalling information transfer readily from individual judgments to group decision-making in situations of intergroup and international conflict. Thus, social psychology along with the other social sciences has raised serious concerns about the rational actor model of decision-making, which initially predominated in both organizational and international studies (Janis and Mann, 1977). The critique contends that decision-making often involves biased information processing, the use of simple heuristics or short cuts, a lack of objective criteria, and a limited search for options. These deficiencies in judgment and decision-making are seen to increase under conditions of stress and fatigue, which are typically present in situations of crisis.

Much of the work on social judgment is now captured in so-called prospect theory, which sees decision-making as involving choices among prospects or options that will yield different outcomes, which have different probabilities of occurrence. As opposed to the rational actor model, prospect theory proposes that individuals evaluate choices not in terms of their absolute value, but in terms of their gains and losses in comparison to the status quo. It also proposes that losses are overvalued in comparison to gains and thus are seen as more important. In decision-making, this bias leads to loss aversion and the taking of greater risks to avoid losses and thereby a tendency to stick with the status quo. When problems are framed in terms of losses, parties are thus more likely to take risks than when they are framed in terms of gains (Kahneman and Tversky, 2000). In application to conflict resolution, these propositions mean that parties are biased toward the status quo, and will see the losses they might incur through negotiating concessions as more important than the gains they might achieve. Hence, mutual dissatisfaction with potential outcomes in a peace agreement results in stalemate rather than settlement.

Another contribution of social psychology to the study of decision-making is the model of groupthink that describes the process by which an insulated and highly cohesive group engages in concurrence seeking to the extent that it overrides the realistic appraisal of alternatives, thus leading to poor decisions (Janis, 1982). Such a group overestimates its own capability and morality, exhibits closed mindedness in which stereotypes and rationalizations are prominent, and censors itself in supporting the initial direction provided by a powerful leader. As a result, the group shows incomplete information search, biased information processing, inadequate risk analysis, and a lack of contingency plans. Although the model and the research on which it is based have been criticized, it has also been supported and elaborated to stand as an important counterpoint to the rational actor model.

As conflicts escalate, a number of fundamental transformations occur in the issues, tactics, and motives of the parties (Pruitt and Kim, 2004). At the highest level of escalation in protracted conflicts, an insidious process known as entrapment becomes a driver of intractability. Entrapment is seen as a cognitive trap in which the parties become increasingly and unwittingly committed to destructive and costly courses of action that would not be predicted by the rational actor model. Thus, the parties expend increasing resources to prosecute the conflict, in part to justify the investments they have already made and hopefully to compensate for the losses they have already incurred. This phenomenon can be partly explained through the functioning of postdecision dissonance reduction, in which a chosen alternative is subsequently evaluated more positively in order to reduce the cognitive dissonance created by its earlier choice. Thus, parties lock into courses of action which do not add up in terms of costs and benefits, but which are cognitively consistent and also privilege losses over gains as predicted by prospect theory.

Another line of work on the social psychology of decision-making focuses on the cognitive or integrative complexity that leaders and other policymakers demonstrate in their thinking and communication about a conflict (Conway et al., 2001). Integrative complexity is demonstrated by a number of indicators, including the extent of search for new information, the rigidity or conditionality of perceptions, and the number of options being considered. These indicators can be grouped into overall measures of cognitive differentiation or the number of dimensions used in interpreting information and cognitive integration or the degree and nature of connections among different elements. Research supporting the role of integrative complexity demonstrates that it tends to decrease during international crises that lead to war and tends to increase

during periods of agreement among leaders. While some of this effect may simply be due to the rhetoric used in situations of conflict, it is likely that it tells us something about the cognitive functioning of policymakers engaged in international and other crises.

Ethnocentrism, Social Identity, and Social Dominance

The concept of ethnocentrism, developed in the disciplines of sociology and anthropology, has been incorporated as an important element of the social psychology of conflict analysis. Referring initially to a tendency of social groups to be ethnically centered in that they see themselves to be superior while holding other groups in contempt, ethnocentrism has been largely cast as a form of generalized prejudice toward all manner of out-groups. Ethnocentrism took a lead position in the development of realistic group conflict theory, which posits that real conflicts of interest cause intergroup conflict. Incompatible goals and competition over scarce resources are seen to result in real threat, which increases in-group solidarity and awareness of identity, causes hostility to the source of the threat, and increases ethnocentric reactions (LeVine and Campbell, 1972; Sherif, 1966). As ethnocentrism moves to higher levels, it is predicted that the cognitive distortions noted above increase in the direction of more extreme stereotypes, negative enemy images, and influential self-serving biases.

A more recent line of theorizing, social identity theory, puts less emphasis on real conflicts of interest and more on the processes of social categorization and identity formation in causing intergroup conflict (Tajfel, 1982). It appears that the mere fact of categorizing individuals into groups gives rise to a perception of heightened similarity within groups along with exaggerated differences among groups. Identity groups are typically defined in ethnic, racial, religious, cultural, or national terms and are the object of identification by their members in ways that constitute an important element of their social identity. It is posited that individuals strive to enhance their self-esteem, which in part derives from the social groups to which they belong, resulting in motivation to achieve and maintain a positive social identity. This leads to making favorable comparisons with other groups, in which one's own group is seen as distinctive and held in higher regard, while other groups may be the objects of derogation and discrimination. In this way, a different explanation is offered for ethnocentrism in comparison to realistic group conflict theory. At the same time, the two theories can be seen as complementary, in that both help explain the insidious power of group and intergroup dynamics to exacerbate conflicts of interest.

Social dominance theory augments the above two theories by affirming group differences in power and status while also explaining individual differences in out-group discrimination (Sidanius and Pratto, 1999). Individuals vary in their social dominance orientation, and those who are high on social dominance support ideologies and policies that legitimize hierarchies among groups, and individual and institutional discrimination in favor of more powerful groups in the hierarchy. Social dominance theory thus complements both realistic group conflict theory and social identity theory by adding a dimension of individual differences, much like the syndrome of authoritarianism, which can help explain the causation and maintenance of conflict between different groups in society.

Escalation and Intractability

Conflicts of interest and identity when not handled constructively have a built-in tendency to escalate, that is, to become more intense and hostile, to involve more issues and parties, and to engage the parties in more contentious and coercive strategies (Fisher, 1990; Pruitt and Kim, 2004). Escalation tends to feed on fear, threat, defensiveness, and reciprocity. Out of fear of losses, parties tend to threaten or carry out controlling or coercive actions to advance their goals, moves which are then reciprocated by the other party following a general law of human behavior: you give what you get. As intensity increases, all of the perceptual and cognitive distortions and errors become more pronounced. Enemy and mirror images move from a dimension of good versus bad to one of virtuous versus evil, while expectations of intransigent or destructive behavior are fulfilled, thus legitimating further attempts to threaten and control. Patterns of communication and interaction move from words to actions and to direct attacks designed to injure. Issues shift from a concern about interests to matters of identity and ultimately to a question of survival. As conflict escalates, the intent becomes not simply to reach one's goals but to eliminate the other party. In this process, the other becomes demonized and dehumanized so that all manner of actions are justified, often leading to a situation of mutual victimization. However, when one side has a clear power advantage, the victimization is unilateral and can result in extreme destructive outcomes as in mass killing and genocide.

The protracted nature of destructive conflicts in many spheres has led to growing interest in the phenomenon of intractability, by which conflicts are enduring or long lasting, remain at a high level of intensity with sporadic outbreaks of violence or other destructive behavior, and are also extremely difficult to deescalate and resolve. These conflicts may be based in a history of domination and injustice by one group over another, may involve very significant issues or resources at stake, and may engage controversial moral or ideological issues, which in a sense are not resolvable. Intractable conflicts often threaten group identities, well-being, or survival, and thus engage a high level of emotional intensity, which further fuel cognitive distortions and aggressive behaviors. At the same time, these conflicts are inescapable in that they involve members of the same family, entities in the same organization or community, or identity groups interspersed in the same territory and political system. Such conflicts present the greatest challenge to methods of conflict resolution, which clearly have to grow in complexity and effectiveness in order to reduce the human costs of destructive, protracted conflict (Coleman, 2011).

Conflict Resolution

Once social science understands an undesirable phenomenon such as destructive conflict, the next question is what practices and policies can we provide to ameliorate the problem. This is the challenge for the interdisciplinary field of conflict

resolution, which has grown up over the past several decades, and to which social psychology has made unique and important contributions. Social psychologists have provided ideas to both improve traditional methods of conflict management such as negotiation and mediation, and have led the way in helping to develop unique methods to address protracted, identity-based conflicts under the rubric of interactive conflict resolution (Fisher, 1997).

Conflict Management Styles, Negotiation, and Mediation

Conflict resolution refers to both the process of addressing difficult conflicts and the outcomes of the process, which must be mutually acceptable and beneficial and are self-sustaining and adjustable to changing conditions. As such, conflict resolution deals with both the objective issues in dispute and the subjective or human elements in minds and in the relationship of the parties. Conflict management is used more to connote dealing with continuing disputes over tangible interests within the context of a generally satisfactory relationship between the parties. In either case, the field prescribes that a cooperative yet firm approach is the best way to successful management or resolution. In this regard, social psychologists were the first to postulate that two dimensions of behavior were required to adequately represent different orientations or styles for addressing conflict: assertiveness or concern for self and cooperativeness or concern for the other party (Blake et al., 1964). Placing these two orientations as the axes of a two-dimensional space yields five distinct conflict management styles: competing, avoiding, accommodating, compromising, and collaborating. While these styles were initially developed to help understand and deal more effectively with interpersonal conflict, they also have relevance to the intergroup and international levels. Each style is seen as having its advantages and disadvantages and each is more applicable in certain situations of conflict and relationship, thus leading to the idea that styles can be adapted to different conflict situations for maximal effectiveness.

Moving to the method of negotiation, by which parties interact to develop agreements that regulate their behavior and typically divide resources, we also see the imprint of the firm yet cooperative approach. Traditional hard bargaining exemplifies a firm approach to the point of relentless competition, whereas social psychologists have contributed to a cooperative and integrative approach in which a party works to meet some of its own interests but is also amenable to the other party meeting some of its interests (Pruitt and Kim, 2004). This results in mutual benefits as well as mutual concessions with outcomes that are more satisfactory and more sustainable over time. The term 'win–win' was coined by Blake et al. (1964) to capture this phenomenon. Social psychologists have been at the forefront of developing models, propositions, and techniques for negotiation that maximize the potential for integrative outcomes.

Mediation is a method of third-party intervention typically applied in conflicts where interaction or negotiation by the parties has not been able to achieve either a one-sided or mutually acceptable outcome. Mediation is a voluntary, nonbinding intervention designed to achieve a negotiated agreement on the objective issues in dispute, and is typically carried out by an impartial, credible, and trusted intermediary. Social psychologists have contributed to the study and practice of mediation in general (Kressel et al., 1989), and have also emphasized the distinction between pure mediation and power mediation, in which the basic functions of persuasion and the creation of options are augmented by the application of leverage (the use of rewards and punishments) by the third party in order to manipulate the parties toward agreement. The use of power mediation, particularly at the international level, continues to raise theoretical, practical, and ethical questions that require continuing attention.

Interactive Conflict Resolution

The failure of traditional methods of conflict management to achieve mutually acceptable agreements and peaceful, sustainable relationships between parties locked in destructive and intractable conflict led the field of conflict resolution to develop alternative and innovative methods. Many of these attempts can be captured under the rubric of interactive conflict resolution, which refers to third-party facilitated, small group discussions involving dialogue, analysis, and problem solving that bring influential participants from parties engaged in destructive conflict together in order to mutually diagnose their conflict and to develop jointly acceptable options for resolving it (Fisher, 1997, 2005). Interparty dialogue is an initial form of this approach, but the exemplar method is that of the so-called problem-solving workshop, which is convened and facilitated by a third-party team of skilled and knowledgeable consultants. As opposed to mediation, which seeks agreement on substantive matters and tries to work around emotional issues, the third-party-consultants in problem-solving workshops address both objective aspects (territory, form of government) and subjective elements (perceptions, attitudes, and relationship issues such as mistrust) in the conflict. Thus, the role requires human relations and small group skills for understanding, communication, and problem solving as well as knowledge from social science about destructive conflict and its resolution. Interactive conflict resolution can also include other methods, such as conflict-resolution training, which brings antagonists into the same educational setting to learn about concepts for analyzing conflict and methods for addressing it; cross-conflict teams, who work cooperatively on projects in peacebuilding; and reconciliation, which facilitates postconflict interactions to reestablish harmony and cooperation.

The rationale for interactive conflict resolution is based squarely in the social-psychological approach to and analysis of conflict provided above. Thus, it is assumed that conflicts are a mix of objective and subjective factors, both of which must be addressed for resolution, and that subjective elements play a larger role as conflict escalates, thus increasing the relevance and applicability of interactive methods. It is also posited that constructive and authentic face-to-face interaction between the parties or their representatives is necessary to confront and overcome the distorted and inaccurate perceptions and cognitions, and to change the competitive, adversarial orientations and interactions of the parties. Given the system orientation of the social-psychological approach, it is also clear that any individual changes in cognitions and orientations that occur among participants must be

transferred to both policymaking and the public discourse among the conflicting parties for deescalation and resolution.

The Problem-Solving Workshop: Characteristics and Goals

Problem-solving workshops are often appealing to parties locked in destructive conflict because it provides an informal, quiet, neutral, low risk, and noncommittal forum compared to official avenues such as negotiation, mediation, or arbitration. In this way, the method has similarities to back channel or secret negotiations between parties, but it must be emphasized that the workshop does not engage parties in negotiation. In contrast, it is designed to explore the issues in the conflict, which must eventually be negotiated and agreed upon; thus, such interventions have often served an important pre-negotiation function. Workshops can assist the parties in understanding their different and common interests, and in distinguishing their positions on issues from their deeper interests, values, and needs. On the subjective side, such encounters can help clear up misperceptions, increase understanding about the conflict dynamics, and build trust, reassurance, and cooperation between the parties. Alongside negotiations, workshops can be used to analyze particularly thorny issues or to provide exploration of anticipated future issues. In the postnegotiation phase, the method can be useful for dealing with implementation difficulties associated with agreements and for building reconciliation between the former antagonists. Thus, the potential complementarity of problem-solving workshops to official interactions is evident in all phases of conflict resolution.

In terms of implementation, the problem-solving workshop is a small group discussion method with only five or so participants from each party (usually only two) and from the third-party team, although larger workshops can be designed wherein a number of problem-solving groups engage in parallel discussions, the results of which are then brought back to plenary sessions. Workshops typically take place in neutral, secluded, and residential settings and last for approximately 4 to 6 days. Participants are unofficial yet influential opinion leaders or advisors who are well-connected to policymakers and/or the public discourse on the conflict through roles such as journalist, author, or academic. Often participants are at the midlevel of their societies, so that they can connect to the leadership above, but also to the wider society below in term of having access and influence. Typically, a rough agenda for discussion is provided, which moves from exchanging experiences and perspectives on the conflict with attention to underlying interests and concerns (particularly needs and fears), to a joint diagnosis of the conflict, and to the mutual creation of options for deescalation and resolution. The role of the third-party consultants is enacted through a number of strategic functions: increasing problem-solving motivation, improving communication, regulating the interaction, and helping to diagnose the dynamics of the conflict. To maintain the quality and respectfulness of the discussion, the participants are held to a number of ground rules or norms of interaction that include items such as no personal attacks, the sharing of air time, analytical discussion rather than debate or argument, and confidentiality in the sense of no attribution of statements to individuals following the workshop. Thus, the problem-solving workshop provides a rare and very different forum for discussion from that to which the parties and participants have become accustomed to in the hostile and adversarial field of the conflict.

As implied above, the problem-solving workshop has multiple goals at several levels of analysis. For individual participants, it is expected that they will experience increased understanding of the conflict and the other party, and that their attitudes to each other will undergo increased complexity and positiveness. They should also develop an increased sense of trust and cooperation toward the other party, and will then work to transfer these attitudinal and relationship changes back to their respective constituencies. This may include contributing new realizations and ideas to negotiations and policymaking along with attempting to positively affect the political discourse and atmosphere in each constituency in ways that support a sustainable resolution. Given that the large gap between a small number of participants and their groups or societies, it is clear that the transfer process is the greatest challenge facing the method; nonetheless, an increasing amount of evidence shows that it is not an insurmountable one (Fisher, 2005).

Problem-Solving Workshops: Rationale in the Intergroup Contact Hypothesis

Some of the rationale supporting the problem-solving workshop can be found at the individual- and group-levels of analysis, but the most powerful explanations for its utility in resolving intergroup and international conflict are to be found in the so-called contact hypothesis (Hewstone and Brown, 1986). At the individual level, the workshop interaction provides new and challenging information about the other party that contradicts the erroneous and simplistic misperceptions and stereotypes common in intergroup conflict. This produces a more differentiated and realistic image of the other group, and also creates cognitive dissonance in the participants that can be reduced by changing their attitudes and orientations in more positive and cooperative directions. In addition, common attribution errors may be identified and countered in the analysis, leading to a decrease in mutual blaming and victimization. In relation to group identity, participants may come to realize that accommodating to the other's need for identity does not mean denying one's own identity, and that recategorization of identities is possible in that overarching dual or multiple identities can be formed, such as different group identities being accommodated in the same national identity.

The intergroup contact hypothesis has been one of the primary contributions of social psychology to intergroup relations, and states that contact and interaction between members of different and conflicting groups can result in positive attitude and relationship change, if it occurs under specified facilitative conditions. These include a high degree of acquaintance potential so that participants get to know each other are persons, equal status in terms of educational and professional accomplishments, social norms supporting open and respectful interaction, a cooperative task and

reward structure that has participants working and achieving together, and a selection of competent and responsible individuals as participants. It is immediately apparent that the design of the problem-solving workshop is geared to implement these facilitative conditions. However, it is essential that the social identities of the participants remain salient in the interaction, so that as participants build bonds of interpersonal attraction they also regard members of the other group as typical rather than exceptional. Thus, any attitude changes should generalize to the other group at large.

Problem-Solving Workshops: Transfer and Effectiveness

The systems approach requires that the workshop method elucidate and evaluate how changes in individual participants' attitudes, understandings, and orientations might be translated into changes in policymaking at the elite level and in the political discourse and atmosphere at the societal level. Transfer is identified as the process by which individual effects and group products (principles, proposals) are moved from the unofficial intervention to the official and public domains (Fisher, 2005). At both the elite and societal levels, effective transfer would mean that a perceptual shift takes place in both parties that sees the other party as responsible and approachable, and thus as a valid partner for negotiations to address the conflict. This also involves a shift from a competitive to a cooperative orientation that supports nonviolent bilateral interaction to manage the differences that have led to the conflict and its escalation.

Most of the evidence supporting transfer effects is anecdotal and provided mainly by the consultants who carried out the interventions. In some cases, research studies of specific interventions have used interviews and other methods to collect information from participants and interveners on the perceived effects of workshops. Recently, the comparative analysis of multiple cases of intervention has been carried out to produce more valid and generalizable results. These studies taken together generally support the theory of practice that is spelled out above and that has been implemented over the past five decades in all regions of the world to address violent ethnopolitical conflicts. When focused mainly at the elite level, the research indicates that the targets of transfer have been decision-makers, policymakers and negotiators, and that the most common objective has been to provide a prenegotiation function to help initiate and inform official talks. Transfer has taken many forms from cognitive changes to creative ideas, and from proposals to increased connections across conflict lines and also between unofficial and official actors within the same party. In a number of difficult cases, it is apparent that problem-solving workshops have made important contributions to successful peace processes. These contributions have usually been in line with a contingency model of third-party intervention, in which methods are matched to the level of escalation and then sequenced to deescalate and resolve the conflict (Fisher, 1990). Regardless of some success, it is also clear that escalated, identity-based conflicts with a high degree of power asymmetry are extremely resistant to both unofficial and official attempts at resolution.

Conclusion

The social psychology of conflict analysis and resolution has provided insight into the causation and escalation of destructive conflict, particularly through the identification of perceptual, cognitive, and interactive processes that tend to exacerbate incompatibilities. A variety of structures and biases in people's minds attend conflict and its escalation in ways that distort social reality and drive adversarial and coercive strategies. Group-level factors amplify and augment individual cognitions leading to rigidity, ethnocentrism, and intractability. In addition to making contributions to the understanding and effectiveness of negotiation and mediation, social psychologists have led the development of small-group interactive methods for analysis and problem solving, which offer an innovative and unique possibility for humankind toward the resolution of complex and protracted conflicts. The problem-solving workshop is the prototype of interactive conflict resolution that has been applied to escalated identity conflicts with some degree of success in terms of contributions to peace processes.

Abstract

There are widely differing conceptions as to whether healthy social relations are, in essence, conflictual or consensual; such differences give rise to different approaches to finding peace and managing power. This article outlines the two broad schools of thought from conflict theory (in which society functions through competition) and consensus theory (which sees society developing through cooperation). It outlines the middle ground between them, as found by pluralism and agonism, before considering the ways in which assumptions vis-à-vis conflict and consensus are reflected in different models of democratic system and, in particular, different priorities for post-conflict recovery.

Introduction

Social and behavioral science has traditionally been dominated by the presumption that conflict and consensus are oppositional: conflict arises from incompatibility and consensus arises from compatibility. This is reflected in two differing schools of thought as to the fundamental nature of society and collective decision-making within it. One can be broadly described as 'conflict theory,' whose proponents view all social action largely within the terms of some form of antagonism or imbalance. The other we can categorize here as 'consensus theory,' which sees progress in society as only being possible through negotiation and cooperation. This article outlines the key features of each approach and the insights they offer before turning to examine different interpretations as to the relationship between consensus and peace. The article's conclusion draws on a range of disciplines in its argument that, far from being polar opposites, conflict and consensus are two sides of the same coin: both conflict and consensus are equally essential to the functioning of society and group relations within it.

Nature of Conflict

Conflict is more than mere difference; it arises from a direct clash in the values or goals of protagonists. The presence of conflict thus infers none other than a win/lose outcome, in which one set of values or goals takes precedence over others. Power is at the heart of this dynamic; conflict is a struggle for power, i.e., the capacity to enact values or goals that annul those of others. And the process of articulating these values and goals among groups thus becomes, by necessity and definition, a political one. This may be seen in all forms of conflict in society. Class conflict, for example, centers on a fundamental inequality of power that spirals out from differential access to resources. Racial or ethnic conflict arises from a challenge to the values and goals of a dominant group that legitimates, and indeed benefits from, the subjugation of other racial or ethnic groups. Gender conflict also, in its simplest terms, is about an inequality of power as a consequence of the prevailing values and goals. Conflict in all these cases arises from group recognition of such a power imbalance and, in some cases, of collective movement to redress it. Into this mix come leadership, ideology, and mass opinion: all of which, again, indicate the centrality of power.

Conflict Theory

At the core of conflict theory – in its myriad of guises – is the belief that power (or, more specifically, an imbalance of power) is fundamental to social relations. Social interaction is thus, in essence, a struggle for control. Further to this, the decisions, identities, and perceptions arising from social exchange are imbued with conflict: 'this way, not that,' 'us not them,' 'mine not yours.' This merging of contradiction with power results in fundamental inequalities permeating throughout all society.

The major conflict theories center upon the most predominant forms of inequality. Marxism, for example, is founded on the premise that material inequality is the most significant of all power imbalances in society. Thus, struggle between classes (the laborers and the capitalists, as Marx (1867) would have it) is the overarching trope of western society, permeating into all forms of political, social, and economic behavior and outcomes. Where Marxian analysis differs from other conflict theories, however, is in its assertion that pervasive social conflict is primarily a by-product of the dominance of capitalism and thus will be eliminated when a more equitable form of exchange supplants the capitalist system.

The use of the notion of 'conflict' to explain the development of modern society reemerged in the 1950s, particularly in sociology departments in American universities. A sociologist, Wright Mills (1956), who applied conflict theory to advance understanding of the effects of social structures on individuals in the modern age, argued that the most influential public institutions are founded, not on agreement, but on conflict and competition. Their role ever after, he claimed, has been to perpetuate stark inequalities in resources and influence, with the result that social norms, values, interests, and decisions thus all come to be shaped by a powerful elite. Social order is thus ensured by coercion applied, through various means, by those with power. Society is consequently stratified, with access to advantage tightly restricted to groups already enjoying social privilege.

Whilst Mills shared Marx's negative view of conflict, other theorists have argued that the pervasiveness of conflict at every level of society makes it, simply, essential to its functioning. A contemporary of Mills, Lewis Coser (1956), claimed that conflict must be recognized as a fundamental element of human relationships. He argued that the struggle for resources and recognition behind conflict serves the vital function of stimulating social innovation and change. Coser built on the work of Simmel (see below), particularly in his focus on the role of conflict in the creation and maintenance of group identities. Conflict acts as a means of socialization, through which mutual antagonism can enhance group solidarity and preserve social stratification. From this perspective, Coser critiqued overtly stable social relationships, rigid social structures, and processes of centralization for making violence and dissent more likely and more intense. Instead, he argued, social conflict itself should be tolerated as naturally functioning to raise awareness of common norms, instigate conformity to laws, and, over time, to generate new social structures. Such positive analysis of the role of conflict was extended in the next generation of US-based sociologists, among whom Randall Collins (1975) made the contribution of further elaborating the links between the macro-context and the micro-level of personal interaction and behavior. The constant struggle for status of each individual – and the conflict this entails – only makes sense if one appreciates the stratified environment in which (s)he lives. The conclusion he drew from this was that, whilst inequality and conflict predominate in modern society, competition and control are the drivers of stability and progress within it.

Consensus Theory

A contrasting approach to understanding social and political relations is to emphasize the vital role of consensus in society. Durkheim (1893) argued that the most interesting aspect of society is not its various dysfunctional elements but, rather, the fact that it functions at all – something that he attributes to the primacy of consensus in successful, healthy social relations. Social cohesion is founded on the interdependence of peoples, forged by social ties that range from kinship to the exchange of services. This functionalist interpretation sees all parts of society as working to uphold its solidarity and to minimize instability. Societies survive, Durkheim argued, by commitment to a common set of beliefs and practices – a form of 'collective conscience' thus functions as the bedrock of social order. Durkheim claimed that this solidarity was created in a 'mechanical' way in traditional societies, using rules to emphasize homogeneity and conformity; in more advanced, differentiated societies, he argued, rules instead regulate differences, necessitating a more 'organic' form of solidarity, or common purpose, between citizens. Durkheim's thesis on solidarity was advanced by Finnish sociologist Erik Allardt (1970) in order to explain different reactions to modernization in the mid-twentieth century. He observed that, in order to function optimally, a modern society needed to have a highly developed division of labor together with a high degree of tolerance and pluralism. A weakness in Communist industrial societies, he therefore argued, lay not in the extent of the division of labor but in their imposition of conformity.

That said, theorists in this tradition have conceded that consensus does not naturally occur but is sometimes founded – and sustained – through coercion (Shils, 1972). Yet a process of socialization in modern societies modifies the behavior of individuals as they learn how to conform, or at least what is 'acceptable,' to the society in which they live. Interaction between individuals and groups can hence be premised on an understanding of how each can be reasonably expected to behave, i.e., the role each will perform (Parsons, 1951).

The nature of consensus changes with the nature of social communication and interaction. In the digital age, consensus may be achieved (or at least sought) through social media and online networks, for example, as much as through persuasive political rhetoric or interpersonal influence. Just as Simmel (1955[1908]) noted the effects of industrial capitalism and modernization on the nature of social organization, solidarity, and choice, so others, a century on, have sought to demonstrate the effects of the new information society on social bonds and relationships (Castells, 1996; Bauman, 2006). Even though the nature and style of communication between individuals has radically changed, however, their interdependence (or, to put it differently, their lack of freedom of choice) remains as strong as ever.

It is important to note at this point that consensus differs from consent in that the latter indicates that each person concerned offers his or her agreement, whereas there is an implicit assumption of majoritarianism in the concept of 'consensus,' given that only 'general' assent need be given. One might say that, rather than explicit and unanimous agreement as to the destination, consensus requires only shared sentiment as to the intended direction of travel.

Such consensual sentiment is maintained by a commonality that is underpinned by shared attachment to core sociopolitical institutions and acceptance of the norms and laws they promulgate. This is not to say that interests and identities do not diverge (this is inevitable in a plural society), but in cases of conflict between groups or individuals, adjudication takes place with reference to these 'common' interests and identities (as defined by laws and rules) and thus consensus ultimately prevails.

Given the close interdependence of society, social and individual needs are best addressed through cooperation rather than competition (which would merely risk generating new problems and divides). If shared norms, values, and institutions are the essence of a healthy society, consensus theorists conclude, conflict is almost pathological.

Pluralism

A tentative 'bridge' between conflict theory and consensus theory emerged in the mid-twentieth century in the form of pluralism. Pluralism recognizes that society is fragmented into diverse groups that compete for resources and have conflicting interests but acknowledges this does not automatically result in nontraversable gulfs crisscrossing society. Instead, Dahrendorf (1959) argued, advanced industrial society has found ways of

finding agreement between these social groups, despite their conflicting interests. Moreover, stability (and change) is realizable through institutionalizing this conflict, such as in the role of trade unions in processes of arbitration with employers. Dahrendorf thus allows for a functionalist emphasis on the role of social institutions whilst maintaining a focus on the differential levels of authority in any society and their effects on sustaining conflict.

Dahl (1967) brought pluralism into political analysis with his vision of society as a mass of competing interests. He argued that inequitable power and control was behind the construction of identities, capacities, and concerns of social groups. Social order is thus only achieved by finding a natural equilibrium among society's component parts, with the state acting as an 'honest broker' as groups battle it out for influence and resources. And the nature of this struggle is neither overt conflict nor consensus, but endless bargaining and compromise.

Indeed, the politics of compromise has been advocated (by Bellamy, 1999) as the logical response to the plurality of identities, values, cultures, practices etc. in contemporary society. He argues that the sheer complexity of the sources and ties of social plurality today makes compromise a necessity, in that the dialogue it allows between incommensurable demands is itself a process to be welcomed and facilitated in liberal democracy.

Consensus versus Conflict?

The matter of what should be set in place after violent conflict remains, ironically, contentious in both theory and practice. The perennial debate as to whether the eradication of conflict is either possible or desirable is to the fore here. On the one hand some claim that the resolution of conflict has to be at least the aspiration of peacemakers. Galtung (1969), for example, identifies the structural and cultural violence (such as poverty, oppression, or corruption) behind conflict as something to be challenged by the goal of 'positive peace.' Others argue that conflict is a necessary element of democracy and social exchange. For example, Foucault (2003) inverted Clausewitz' dictum (on war as politics by other means) to define politics as war waged nonviolently by the state. Peace, thus, entails some form of conflictual power struggle. This is, to some degree, in line with the tradition of agonism, which seeks to acknowledge and foster the positive benefits of conflict for democratic society (Schaap, 2009).

Yet there is common ground to be found between these standpoints because conflict and consensus are not mutually exclusive. First, the traditional 'criss-cross' theory of conflict prevention assumes that the intersection of group identities and lines of transmission reduce the risk of violence (Galtung, 1966); but for conflict to be present at all, there needs to be at least a minimal degree of communication and connection between the competing parties. Second, all but few agree that deep differences among groups should be expressed politically rather than violently. But this gives rise to the problems of determining how best to give political voice to the groups concerned and the basis on which the power is divided between them.

Power-Sharing

Different conceptions as to the nature of society result in different constructions of the democratic state. The assumption in conflict theory that democracy centers on a constant struggle for dominance between divisions in society views adversarial politics as the most effective mode of decision-making. On the other hand, democratic institutions founded on the principle of consensus seek to incorporate a wide spectrum of opinions and to generate agreement rather than mere decisions. Consensus democracies, therefore, generally need a different electoral system to that in majoritarian systems, one which allows for proportional representation of the groups that constitute the population. This in turn requires greater political mobilization among a wide range of social clusters than in other forms of democracy.

The type of democratic institutions put in place after violent conflict are often intended to build-in agreement to executive and legislative decision-making and can thus be modeled on a form of consensus democracy. Consociationalism, a system originally conceived from the case of Dutch democracy as one proven capable of creating consensus across deep social cleavages, has been advocated as a model for power-sharing in other divided societies (Lijphart, 1977). Proponents of the consociational template for democracy after conflict argue that it guarantees all cleavage groups a proportionate input in policy and executive decision-making and that it minimizes the potential for systemic discrimination (Noel, 2005). Key features of consociationalism that lend themselves to finding post-conflict stability include executive power-sharing, (segmental) autonomy, commitment to proportionality, and veto rights (McGarry and O'Leary, 2006). Cases of the application of consociationalism, or a version of it, after conflict include the system of government in Bosnia-Herzegovina established by the 1995 Dayton Agreement and Northern Ireland's devolved executive after the 1998 Good Friday (Belfast) Agreement.

Consociationalism has had many critics, however, many of whom point to the elite focus of the model, in particular its reliance on power-holding elites to bring cooperation to the heart of the democratic institutions and for their lead to be willingly followed. Problems can arise for example, if the political elites are unable to bring their constituent supporters with them (as in the first years of the Northern Ireland executive), if deep inequalities between social groups remain unameliorated (as in Lebanon), or if the consociational constitution is repressively prescriptive (as in Fiji).

An alternative model of democracy after conflict is centripetal, i.e., one which seeks to concentrate political momentum toward the center ground between parties rather than allowing it to fester at the extremes. This model follows Horowitz (1985), who argued that intergroup cooperation ought to be made a condition for electoral success rather than, as with consociationalism, seen as a hoped-for outcome of power-sharing. Centripetalism also seeks to avoid the reification of ethnic identities that is seen as a danger in consociationalism by manufacturing incentives for interethnic and centrist politics (Reilly, 2001).

Peacebuilding with Consensus

Strong criticisms of both consociationalism and centripetalism are put forward by integrationists, who argue that such theories underestimate both the unifying potential of the state and the peacebuilding capacity of nonelite actors. The importance of local ownership of peace processes requires decision-making mechanisms that reach through to the grassroots. Donais (2012), for example, goes so far as to say that peacebuilding should be pinned to the concept of consensus-building, given its insinuation of inclusivity. Only by seeking consensus at all levels of the conflict-ridden society and at all stages of a peace process, it is implied, can that process be truly 'owned' and embedded and minimize the risks of further alienation or disaffection from the political sphere (Richmond, 2012). This approach is posed as an alternative to the dominant one of liberal peacebuilding, which is primarily a political, top-down process in which international support can be seen as more important than local endorsement. Consensus is thus coming, in twenty-first century peacebuilding, to be predominantly interpreted as a requirement to recognize and engage with the needs – and the wisdom – of the local population.

Conflict, Consensus, and Crisis

In the globalized world of the twenty-first century, there are new modes of conflict and consensus in developed societies. These came together in the case of the Occupy movement, which attempted to address stark extremes of social and economic inequality through new mechanisms of consensus-building. According to the slogan of the movement, 99% of the mass population was counterpoised against the powerful elite of 1%. As prime locations in international city centers in 2011–12 became occupied, the movement embodied innovation in finding consensus. In small urban protest occupations it used ancient means of human voices and coordinated hand signals (see Figure 1); via the internet, it used new forms of social media to advertise activities, disseminate ideas, and galvanize support locally and internationally. Thus, in the context of global economic crisis, social conflict reached new extremes and social consensus was sought by novel means.

The Occupy movement itself embodied differing conceptions as to whether contemporary social relations are, in essence, conflictual or consensual. As this article has outlined, such varying interpretations of the nature of society give rise to different approaches to the greatest and most enduring collective challenges, such as those of managing power and minimizing violence. Such assumptions also inform how we understand democracy to function and society to develop. But this article has also noted that recent scholarly contributions to the debate have sought to identify a middle ground between these positions, acknowledging not just the necessity of 'both' competition and cooperation in healthy social relations but also the possible complementarity between them. Conflict and consensus, it must be concluded, remain equally essential to contemporary society.

Conflict and Socioemotional Development

Brett Laursen and Amy C Hartl, Florida Atlantic University, Boca Raton, FL, USA

Abstract

Conflict is inherent in growth, and human development cannot proceed without conflict. Intrapersonal conflict reflects competing impulses and desires as well as incongruent information. The resolution of intrapersonal conflict shapes the individual's view of the self and the self's place in the world. Interpersonal conflict is a social episode marked by overt behavioral opposition. The characteristics of the participants and their relationship, the issue, the frequency, and the tactics employed determine the developmental significance of interpersonal conflicts. Adaptive, constructive conflicts are known to facilitate individuation, growth, and positive adjustment. Maladaptive, destructive conflicts hinder development and foster social, emotional, and cognitive problems.

Conflict Defined

Conflict is a broad term, widely invoked in the common vernacular and in the scientific literature to suggest a state of disagreement or opposition. The term carries different connotations depending upon whether the experiencer is singular or plural. Intrapersonal conflict describes a state of emotional turmoil or intellectual dissent that occurs within an individual. Interpersonal conflict describes a social interchange that is marked by opposing goals and that involves two or more individuals. The earliest English usage of each term dates to the fifteenth century; both have common roots in the Latin *conflictus*, meaning throw or strike together (Shantz and Hartup, 1992). This shared etiology tends to muddy distinctions between these two distinct forms of conflict.

A conflict has been likened to a play or novel. In the case of interpersonal conflict, there is a protagonist and an antagonist (conflict participants). In the case of intrapersonal conflict, the protagonist and antagonist come in the form of a thesis and an antithesis. For both interpersonal and intrapersonal conflict, there is a theme (conflict topic), a complication (initial opposition), rising action (conflict behaviors), climax or crisis (conflict resolution), and denouement (conflict outcome). These discrete components combine to form a coherent whole. Plots unfold according to a prescribed sequence and so do conflicts.

Intrapersonal Conflict

Intrapersonal conflict encompasses two broad domains. At the emotional level, conflict reflects competing impulses or desires. Freud (1965) attributed these tendencies to contradictory aggressive and sexual proclivities with origins in the id (the unregulated physical self) and to irreconcilable differences between these selfish urges and constraints imposed by the superego (the social mores conveyed by family and culture). At the cognitive level, conflict reflects dissonance produced by incongruent facts, opinions, or modes of thought. Piaget (1985) attributed these tendencies to equilibration, the innate tension between a preference for stability, and a drive to master the environment. Assimilation encourages stability by incorporating new information into existing mental schema. Should this prove insufficient for mastering the environment, accommodation is required to alter mental schema in a manner consistent with the information available.

Intrapersonal conflict is by definition a private experience. It cannot be observed and it has no reliable metric. Early scientific psychologists relied on introspection to glean insight into thoughts, a practice modified and popularized by psychodynamic psychologists to probe unconscious emotional states. Subjective experience as a topic of study fell out of favor with the behavioral revolution. Reaction times, physiological cues, and projective responses were employed as proxies for inner conflict, but poor reliability and the absence of face validity undermined these efforts. With the cognitive (counter)revolution, new introspective methods gained legitimacy as advances in measurement and instrumentation were applied to mental processes. Scholars began to focus on the diverse experiences of different cultural and ethnic groups, and in so doing it became apparent that scientific inquiry into intrapersonal conflict cannot proceed in the absence of valid and reliable self-report data.

Interpersonal Conflict

Interpersonal conflict may take place at the level of the dyad or the group. Dyadic conflict is a social episode marked by overt behavioral opposition. The function of such conflicts and the manner in which they unfold vary according to characteristics of the participants and their relationship, the issue and context of the disagreement, the tactics employed, and their consequences (Deutsch, 1973). Group conflict refers to negative or incompatible attitudes and behaviors directed by members or representatives of one group toward those of another group. The nature and significance of intergroup conflict differs according to leadership styles and prevailing norms, member cohesion, resource availability, and the individual and collective talents and experiences of each group (Sherif et al., 1961).

Interpersonal conflict is a quantifiable, sometimes public event. It consists of a sequence of easily recognized and well-defined components including the initial opposition and the tactics, resolution, and outcome. Three prevalent patterns have been identified (Adams and Laursen, 2001): (1) coercive conflicts, which include negative affect, coercive tactics, power assertive resolutions, and unequal or unfavorable outcomes; (2) constructive conflicts, which include neutral or positive

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96007-0

affect, cooperative tactics, negotiated resolutions, and equal or favorable outcomes; and (3) unresolved conflicts, which vary in terms of affect and tactics but are similar in that they involve disengagement without a clear resolution or outcome.

Empirical studies of dyadic and group conflicts suffer from inconsistent operational definitions. Conflict measures differ in terms of whether they assess unilateral or mutual oppositions, and in terms of whether the frequency of an event is distinguished from its affective intensity. Distinct patterns of interpersonal conflict emerge when considering reciprocated as opposed to unreciprocated disagreements and when angry disputes are examined apart from the mundane.

Early work on interpersonal conflict focused on groups and dyads in experimenter-contrived conditions designed to elicit disagreements. Concerns about the ethical treatment of participants and a lack of generalizability prompted improvements in ecological validity; unobtrusive observations in natural settings have been integrated with running assessments of psychophysiological states and moment-by-moment accounts of participant cognitions and affect (Gottman, 1994). The utility of self-reports increased once scholars realized that participant reports of conflict differ not only from one another but also from observer reports, suggesting that what was once considered measurement error may in fact represent important individual differences in how conflict is perceived and experienced. It is not uncommon for two individuals to disagree as to whether they were involved in a disagreement. For instance, parents are more likely to describe an interaction as a conflict than are children. Because objective indices of child outcomes are more closely tied to self-reports of disagreement than parent or observer reports, scholars may consider this an instance where questionnaires proffer the best insight into behavior.

The Role of Conflict in Development

Conflict is inherent in growth, and human development cannot proceed without conflict. Wisdom, emotional maturity, and social skills may be tied to a series of developmentally defined tasks and the conflicts specific to each. Conflict outcomes do not exist along a single continuum that runs from the beneficial to the detrimental, with benign outcomes in the middle. Instead, costs and benefits probably represent independent dimensions, each ranging from low to high. Therefore, a conflict can have both positive and negative consequences. For example, stress and anxiety may be an unavoidable part of healthy individuation; conflict that promotes the latter may increase the former. The developmental effects of conflict appear to be limited to specific domains of influence circumscribed by individual timetables and characteristics of the disagreement such as the issue and participants.

Intrapersonal Conflict and Development

Theory concerning the ontogenetic significance of intrapersonal conflict has outpaced research on the topic. There is less research on emotional development than on cognitive and social–cognitive development, but the available evidence supports the assertion that the influence of intrapersonal conflict is defined by the topic of disagreement and the cognitive or affective domain invoked. Intrapersonal conflict arises when a situation offers benefits that make an individual initially approach the outcome rapidly, but also involves risks that make an individual avoid completing the outcome (Lewin, 1935). Indecision results when the risks become more salient than the benefits. Effects are qualified by individual timetables: development moderates the influence of conflict. The likelihood that some developmental periods are more susceptible to alterations than others leads to the provocative suggestion that intrapersonal conflict is neither a necessary nor a sufficient condition for development but rather a factor that may, at certain times, facilitate advances in the specific emotional or cognitive arena in which it arises (Shantz and Hartup, 1992).

Adaptive Correlates of Intrapersonal Conflict

Intrapersonal conflict is thought to be instrumental to the attainment of several important milestones in cognitive and socioemotional development, although it is important to reiterate that empirical research on the topic is scarce. Intrapersonal conflict provides the impetus for cognitive and social cognitive growth and, in so doing, fosters profound shifts in behavior. Put another way, intrapersonal conflict may change the filter through which the world is interpreted and thereby altering motivations for social action.

Mechanisms of Adaptive Intrapersonal Conflict

In the Piagetian theory (1985), accommodation implies the occurrence of intrapersonal conflict that leads to significant developmental changes. Specifically, some forms of intrapersonal conflict prompt changes in internal schema and mental structures, such that prior views are discarded after weighing newly encountered perspectives. Additionally, intrapersonal conflict may alter affect and impulse control. Resistance to temptation can be thought of as a conflict between an immediate reward and a later cost. The strength model of self-control (Baumeister et al., 2007) suggests a mental mechanism akin to a muscle that improves in strength with exercise. Intrapersonal conflict also fosters social cognitive change. With cognitive maturity, the child comes to realize that people hold different views of the world, even when they have access to the same information. The ability to simultaneously consider multiple perspectives prompts advances in moral reasoning commensurate with the abandonment of egocentric views.

Developmental Outcomes of Adaptive Intrapersonal Conflict

Four instances in which intrapersonal conflict may be adaptive deserve mention. Accommodation (Piaget, 1985) exemplifies the first process: a child confronted with a difficult moral dilemma may be forced to disregard views previously held dear in order to objectively consider different perspectives and reach a fair solution. Second, intrapersonal conflict can improve abilities to delay gratification. A child who opts to delay gratification in the hopes of improved rewards will learn to succeed by cultivating strategies that minimize emotional arousal and divert attention from proximate stimuli. Third, role-taking abilities may improve as a result of intrapersonal conflict. A child who contemplates how to obtain goals and overcome obstacles must consider the best means to an end.

A consideration of influence and tactics may foster advances in the perceptions of others. Finally, intrapersonal conflict may force an individual to evaluate goals and establish priorities. As youth consider how to invest their time, effort, and resources they gradually commit to an individual identity.

Maladaptive Correlates of Intrapersonal Conflict

Intrapersonal conflict may also be the cause of adjustment difficulties. It should be noted, however, that the mechanisms have proven hard to substantiate, suggesting that causal evidence for adverse outcomes must be considered tenuous.

Mechanisms of Maladaptive Intrapersonal Conflict

Intrapersonal conflict may arise when the child is confronted with equally attractive (or equally unattractive) alternatives. Alternatively, the child may be presented with information that is inconsistent with specific beliefs or attitudes. Cognitive dissonance (Festinger, 1957) describes the tension arising from the need to resolve competing claims. Positive features of one position or negative features of another will be emphasized and exaggerated until the alternatives are no longer equal, making it easier to select an alternative. Rumination describes an obsessive focus on a dilemma or problem, creating intrapersonal conflict as the individual struggles to shift attention to other matters. Maladaptive intrapersonal conflict also encompasses incongruous urges or impulses. Sigmund Freud (1965) argues that intrapersonal conflict was inevitable as adolescents struggle with emerging sexual impulses arising from the id and societal constraints internalized in the superego during the genital stage. G. Stanley Hall (1904) similarly claimed that inner conflict was an inherent developmental milestone, famously dubbed adolescent 'sturm und drang' or storm and stress. The origins of this inner turmoil come from the contradictory urges and opportunities that accompany imminent adulthood.

Developmental Outcomes of Maladaptive Intrapersonal Conflict

Maladaptive outcomes attributed to intrapersonal conflict are legion. Cognitive dissonance can be debilitating. Failure to resolve dissonance may give rise to physiological stress. Yet the need to resolve dissonance may force the individual to make an ill-timed, uninformed decision. In the process, inaccurate information may be encoded with unintended consequences. Forced to select a partner for an outing, the child may enhance the esteem of one friend in relation to others, unwittingly limiting future social experiences. Rumination can give rise to depression, a logical response to a negative world view. Similarly, normative adolescent intrapersonal conflict may have pathological consequences. Depression may come from perceived powerlessness to control impulses and overcome obstacles. Antisocial behavior and attitudes sometimes accompany perceptions of injustice that accompany the realization that youth often have no control over their opportunities or future.

Interpersonal Conflict and Development

There is considerable support for the premise that the developmental significance of conflict depends on the relationship in which it arises. Three relationship properties are germane: closeness, permanence, and power. Disagreements in close relationships have the potential to alter developmental trajectories profoundly; few disagreements in other relationships have such effects. Disagreements in voluntary relationships are more apt to bring about individual change than those in obligatory relationships; participants in the former must behave in a manner that affords mutually satisfactory outcomes if the affiliation is to continue, whereas participants in the latter worry little about the dangers of relationship dissolution. Disagreements in horizontal or mutual relationships provide especially fertile ground for improved social skills because when power is shared, negotiation is necessary for an amicable resolution; in vertical or unilateral relationships, resolutions are more often the product of power differentials than of negotiation abilities. These variations notwithstanding, developmental shifts in conflict management may be identified such that the practice of coercion is gradually replaced across childhood and adolescence by negotiation and withdrawal as advances in the ability to negotiate during adolescence are accompanied by a growing appreciation of the important role mitigation plays in preserving interpersonal bonds (Selman, 1980).

Frequency also helps determine the developmental significance of conflict (Laursen and Hafen, 2010). Regarding detriments, there are costs associated with the complete absence of conflict because individuals who avoid conflict must suppress their needs. This has deleterious effects on relationships and participants, because relationships that are not sensitive to participant needs are perceived as lacking in closeness and support, which are risk factors for adjustment difficulties. As the number of conflicts increases to moderate levels, the costs associated with conflict should decline. Although conflict is never a risk-free enterprise, moderate amounts of nonabusive discord are not known to predict adjustment problems. As the frequency of conflict increases further, however, the costs associated with conflict should increase sharply. Thus, a positive association between conflict frequency and poor outcomes may be nonlinear, with adverse outcomes increasing as an exponential function of increases in conflict. Regarding benefits, there are few benefits associated with completely avoiding conflict. Up to a point, a positive association between conflict and benefits demonstrates that additional conflicts should be linked to better outcomes. Eventually, a saturation point is reached and outcomes do not improve or decline for those with conflict beyond the optimal level.

The effect of conflict frequency on developmental outcomes depends on an additional factor: relationship quality. In poor-quality relationships, those who avoid conflict may actually be better adjusted than those who do not, because it is unlikely that participants are missing out on conflict experiences that might buffer against adjustment problems. Disputes in unsupportive relationships tend not to have positive consequences. Each successive increase in conflict in poor-quality relationships is likely to bring fewer positive outcomes to the point where conflict offers virtually no benefits for participants. Adjustment problems should increase as a direct linear function of the number of conflicts.

In contrast, there may be costs in avoiding conflict in high-quality relationships because supportive relationships attuned

to the needs of participants may well respond to disagreements in a manner that protects against maladjustment. Avoiding conflicts leads individuals to miss out on the benefits that typically arise from disagreements in supportive affiliations. For this reason, individuals with moderate amounts of conflict in high-quality relationships demonstrate fewer adverse outcomes and better adjustment than individuals with no conflict (Adams and Laursen, 2007). It is probably the case that most benefits can be realized from only a few disagreements, but it is probably also the case that a few more disagreements are unlikely to interfere with the realization of benefits. At some point, however, conflict will become counterproductive and positive outcomes will decline in response to additional conflict. Excessive conflict is expected to correspond with few or no beneficial outcomes, regardless of the quality of the relationship, but it probably takes more conflicts to reach this point in high-quality relationships than in poor-quality relationships.

Adaptive Correlates of Interpersonal Conflict

Social skills and social development are entwined with interpersonal conflict. Conflicts that promote intellectual dialogue and justifications of views are more apt to be beneficial than conflicts that are limited to simple expressions of opposition. The adaptive significance of conflict varies across relationships. Better outcomes accompany those in better relationships. For example, disagreements, especially those arising in close relationships, are one of the primary means whereby individuals define themselves. Constructive conflicts, characterized by productive dialogue and affirming exchanges, should predict more beneficial and fewer detrimental outcomes, particularly when arising in supportive relationships.

Mechanisms of Adaptive Conflict

Three influence pathways merit mention. First, conflict may prompt changes in self-understanding and self-evaluation. Consequential disagreements force participants to reevaluate goals and tactics, offering opportunities to hone social perspective taking, and interpersonal negotiation skills (Selman, 1980). Second, conflict helps to determine patterns of social interaction in close relationships that may impact developmental outcomes. Third, conflict may define and alter expectations about individuals and relationships, such that in some cases roles and responsibilities are negotiated directly, but in other cases behavior is evaluated for cues as to whether current expectations are consistent with the demands of the situation and the maturity of the participants. A prime example of adaptive conflict is when young adolescents seek to gain authority over domains that were once subordinated to parents, especially in areas that concern the regulation of personal behavior.

Developmental Outcomes of Adaptive Conflict

Conflict with peers is thought to be especially critical to cognitive and social cognitive development because differences between relative equals are not typically settled by power assertion but instead require negotiation and perspective-taking abilities. Peer interaction is important not because peers are a more credible source of information, but because conversations between peers involve a unique form of discourse that requires each participant to articulate and defend a position. Social encounters between peers encourage children to reconsider their own views in light of the alternatives proposed, increasing the self-reflection required to discover errors and abandon untenable positions. According to this view, it is not conflict per se that promotes intellectual growth but rather the challenging, constructive dialogue that is embedded within it. Greater cognitive development is more apt to occur following peer conflict than parent–child conflict because of the frequency of exchanges that require elaboration, justification, and critical thought. Conflict with siblings and friends is also associated with greater affective perspective taking and emotional sensitivity, and higher levels of moral development.

Conflict promotes psychosocial development and well-being. Disagreement can enhance mental health and social adjustment insofar as it provides opportunities for improving self-expression and refining interpersonal collaboration skills. Conflict is posited to be an essential part of the process of adolescent individuation. Constructive disagreements between children and parents are positively associated with greater adolescent identity development, role-taking skills, and self-esteem. Conflict with parents serves to promote adolescent individuation and identity development, facilitating the normative process of separation and differentiation from the family. Some disagreement is thought to be necessary for the adolescent to develop a unique identity and to establish autonomy from parents. In addition, conflict may be the impetus that forces parents and adolescent children to renegotiate family roles and responsibilities in a manner that is consistent with the child's heightened maturity. Adolescent ego and moral development have also been tied to constructive family problem solving.

Maladaptive Correlates of Interpersonal Conflict

While some disagreements offer individuals an avenue to define themselves, others delimit social interactions. This can be reconciled with indications that conflict is beneficial insofar as the association between conflict and individual well-being is nonlinear. In this view, some disagreement is required to address problems and facilitate change, but there is a point where most benefits have been realized and additional conflict is counterproductive. Eventually, the adverse consequences of chronic discord overtake the gains that accrue from moderate disagreement. It follows that adolescents who report some conflict should fare as well or better than adolescents who report no conflict because experience managing disagreement may promote competencies that buffer against maladjustment; however, adolescents who report high levels of conflict should fare worse than those who report some or no conflict because unremitting contentiousness undermines self-worth and overwhelms coping mechanisms. Unsupportive relationships and coercive conflicts characterized by hostile assertions and behavior heighten costs and reduce benefits from conflict.

Mechanisms of Maladaptive Conflict

Two influence pathways merit mention. Conflict may lead to patterns of social interaction in close relationships that

negatively impact developmental outcomes. Persistent conflict corrodes closeness. Coercive exchanges tend to be self-perpetuating and, once started, they interfere with the dividends that normally accrue from positive affiliations (Patterson, 1982). Those who rely on coercion to resolve disagreements live in different social worlds from those who use other means to resolve disagreements. This is true in a figural sense, because the same partner will respond to coercion differently than to collaboration. Overtime, chronic hostility breeds maladjustment and troubled youth behave in ways that tend to elicit even greater antagonism. There is also literal truth to the claim that high-conflict individuals live in a different social world than low-conflict individuals. Most people find conflict aversive and seek to avoid it. Those who do not must eventually find themselves in the company of similarly coercive interaction partners, which may heighten disputatiousness, furthering isolation from low-conflict counterparts.

Conflict may also heighten existing problems and pathologies. The consequences of stable personality traits, such as low agreeableness, may be exacerbated when coupled with coercive conflict management strategies. The same may be said for youth with a predisposition for aggression or social anxiety. In each case, conflict may amplify attributes that threaten well-being.

Developmental Outcomes of Maladaptive Conflict

Strong evidence supports the assertion that children who experience high rates of angry conflict suffer from low self-esteem, poor social skills, interpersonal rejection, and adjustment problems. Coercive conflict is especially indicative of later difficulties (Laursen and Pursell, 2009). Much the same can be said of conflict during adolescence and young adulthood. Elevated rates of interpersonal conflict have been linked to adverse outcomes in at least eight areas: aggression, depression, delinquency and deviancy, school grades, health, stress, withdrawal, and relationship difficulties.

Conflict, particularly coercive conflict, is stressful. Negative affect is the primary source of stress arising from conflict; anger activates a fight or flight response which, among other things, may result in an extended period of elevated blood pressure. Chronic conflict may also provoke apprehension and anxiety, which can trigger a host of potentially debilitating physiological reactions. Conflict may foster rumination; when combined with anger and anxiety, rumination elevates risks for depression. Affective arousal also interferes with information processing abilities. The mental and physiological states that anticipate or follow from conflict may adversely impact decision-making skills, with consequences that range from unpleasant to disastrous. Coercion tends to beget coercion; disagreements that spiral out of control can trigger hostility and violence. Poorly managed conflict may foster coercive interpersonal processes that interfere with normal socialization; poor social skills give rise to school difficulties, peer rejection, and affiliation with delinquent age-mates. Finally, conflict may interfere with the supportive functions of relationships, leaving individuals isolated and alienated.

In poor-quality relationships, each successive increase in conflict has been linked to a commensurate decline in outcomes. Increases in conflict from low to moderate levels are linked to greater delinquency and withdrawal for adolescents in poorer but not better quality relationships (Adams and Laursen, 2007). High levels of conflict are never beneficial and appear worse for individuals in better quality relationships, perhaps because expectations of interpersonal harmony are violated by frequent discord. Nonlinear trends are evident in most low-negativity relationships: as conflict increased from medium to high levels, delinquency increased, school grades either worsened or stopped improving, and withdrawal either increased or stopped declining. Thus, negativity exacerbates the difficulties that accompany chronic conflict and inhibits the beneficial consequences of modest conflict by creating conditions of mistrust and apprehension that are antithetical to supportive relationships. Under these circumstances, disengagement from parents and the accompanying renegotiation of adolescent roles and responsibilities may prove difficult, prompting a downward spiral of maladaptation and contentiousness.

Youth who have difficulty getting along with others are at considerable risk. Disagreeable youth have high levels of concurrent and prospective adjustment problems, with rates of depression that rival victimized youth, and rates of antisocial behavior that rival aggressive youth.

Conclusion: The Paradoxical Influence of Conflict

Balance theories of conflict argue that the consequences of conflict depend on the proportion of disagreements that are constructive relative to those that are destructive (Gottman, 1994). Constructive conflicts foster supportive relationships, which promote optimal development. Destructive or coercive conflicts breed antagonistic relationships, which can undermine successful adjustment. According to this view, individual outcomes are more a reflection of the ratio of positive to negative interactions than the absolute number of each. Beneficial conflict outcomes characterize relationships where pleasant interactions outweigh unpleasant ones; detrimental conflict outcomes characterize relationships where negativity outweighs positivity. The ratio of positive interactions to negative interactions may be a better predictor of outcomes than the absolute frequency of either. It follows that conflict may predict adverse outcomes only when it crosses a threshold in terms of the proportion of disagreements to the total number of social interactions or when the number of destructive conflicts exceeds the number of constructive conflicts. Not everyone subscribes to this view. According to some, debilitating outcomes accompany destructive conflicts, regardless of their number or ratio to positive exchanges.

Conflict is often unpleasant and aversive. Given the option, most people would choose to avoid it. For this reason, it is commonly assumed that conflict hinders development. This assumption has been challenged on the grounds that linear models overlook the beneficent role that conflict plays in maturation. A curvilinear model of influence captures this alternative perspective: moderate conflict provides experience necessary for optimal socioemotional development, whereas too little conflict limits the potential for growth and too much conflict overwhelms mechanisms for coping with it. Conflict is not necessarily detrimental, but neither is it intrinsically beneficial; the consequences depend on its frequency, the way

in which it is managed, and the quality of the relationship in which it arises.

Abstract

Archaeologists have a long-standing interest in the evolution of human conflict and war. They identify three modes of aggression and violence based on the archaeological record: self-redress homicides, feuds, and war. Self-redress homicides predominated early in human history and continued among egalitarian hunter-gatherers. Feuds are the typical means of tribal justice for nonegalitarian hunter-gatherers, pastoralists, and small-scale farming communities. Warfare employs organized deadly force by agricultural chiefdoms and various state societies that seek to alter the balance of power between autonomous political communities. The ways in which violent practices are constituted, result in part from the nature and scale of human social organization.

Over the past two decades archaeologists have continued to develop robust models for understanding conflict and war in the past. New geophysical techniques and bioarchaeological methods, for example, are providing key physical evidence of defensive systems (Keeley et al., 2003) and skeletal trauma (Knüsel and Smith, 2014; Martin et al., 2012). Archaeologists are also positing hypotheses concerning the causes and consequences of violence, and working toward assessing how conflict and war have shaped our evolution as a species (Fry, 2013). These studies of past societies are critical for informing us of the human capacity for aggression and violence, as well as cooperation and peace, not only in the past and present, but also for the future.

Critical evaluation of ethnographic studies has sharpened interpretations of past human behavior, and has led to questions central to understanding changes in conflict and war throughout the world (Ferguson and Whitehead, 2000; Fry, 2006; Reyna, 1994). Several questions have traditionally been of interest to archaeologists. How is aggression and violence expressed under varying circumstances? What political and social factors precipitate violence and warfare? What role does conflict and war play in efforts to increase political power, as well as to undermine political centralization? And finally, How is the status quo maintained in the face of conflict and war? The answers to these questions frequently take into account variations in both the intensity and prevalence of conflict and war across space and through time. The evolution of conflict and war is perceived by archaeologists, not from a monocausal perspective, but rather as part of a complex, developing social and political fabric. Such an approach forces the recognition of the multiple processes that give rise to intercommunity conflict.

Egalitarian Hunter-Gatherers and Self-Redress Homicides

Some degree of violence is present in virtually all human societies – people everywhere and at all times possessed the potential to achieve and forward their goals and relations with one another through aggression, conflict, and violence, as well as through cooperative and peaceful behavior. It is important to ask under what conditions different modes of conflict and war vary through time. How is aggression and violence expressed in terms of the scale at which society is politically and socially integrated? To what extent can archaeology document the variability of aggression and cooperation? For example, hunter-gatherer conflict and violence exhibit great range in scale and variation (Kelly, 2013). Archaeological and ethnographic perspectives draw important distinctions in the varying nature of hunter-gatherer conflict and violence: egalitarian, family-level foragers generally lack organized intercommunity conflict, while nonegalitarian, socially hierarchical, and segmented hunter-gatherer violence ranges from feuds to war (Fry, 2006; Kelly, 2000).

Among egalitarian foragers conflicts often erupt over personal grudges, which may be resolved through alliances, avoidance, negotiation, and toleration. When affiliative actions fail, the injured parties might resort to brawls and self-redress homicides – actions undertaken by relatives who seek their own justice in cases of injured or murdered kin. Family-level hunter-gatherer violence is typically limited because they lack the overarching, cohesive kin organizations necessary for coordinating social groups larger than the family. When family-level, organized violence does occur it settles disputes, but it is ineffective for controlling people (Fry, 2006; Reyna, 1994).

Hunter-gatherers were once characterized as living a Hobbesian existence – one of "continual fear, and danger of violent death," in which human life was "solitary, poor, nasty, brutish, and short" (Oakeshott, 2008: 94). But with ethnographic field work in the post-World War II years, this perspective shifted to one where family-level foragers were viewed as 'simple, harmless' people who lived in a state of harmony (Thomas, 1958). Based on more recent research, neither view is entirely justified; a more accurate appraisal characterizes egalitarian hunter-gatherer conflict as violence that might become lethal. In general, conflicts are resolved through a variety of social mechanisms. For instance, South Indian foragers typically exhibit self-restraint to manage group conflicts, in addition to separation (walking away from those who threaten or offend), silence, and tolerance. The Kadar, for example, simply move from one place to another when any harsh words are spoken, believing that one forest is as good as another. The Paliyar upon feeling they have been disrespected, typically refrain from verbal rejoinders or aggressive gestures

 http://dx.doi.org/10.1016/B978-0-08-097086-8.13029-6

such as a shaken fist (Gardner, 2013). These models of hunter-gatherer behavior and lifestyle have had a profound impact on how archaeologists view the past and how theoretical models are constructed for investigating the evolution of conflict and violence, as well as cooperation and peace.

A reevaluation of hunter-gatherer society based on archaeological and ethnographic research now suggests that family-level, egalitarian foragers embraced the politics of nonconfrontation with a general ethos of nonviolence (Fry, 2006). However, when a group's social mechanisms for dispute resolution fail, opponents may come to blows. And when violence does occur, it typically takes place within the social group, being confined to the adjudication of murders that usually result from pursuits over women, reactions to insults, and revenge for prior homicides. Overall, egalitarian foragers tend to have low rates of violence, typically limited to brawls or fist-fights, and rarely feuds. Aggression is relatively harmless, and while it is considered inappropriate to show anger, violence may erupt into a melee with no particular objective other than expressing pent-up frustrations resulting from personal grudges. For example, among the Mbuti of the Democratic Republic of the Congo disputes might erupt every 3 to 4 days (Turnbull, 1965). Certainly, such anger may become lethal, but violence is a product of an individual's own rage and not the calculated risk of one group choosing to raid another group for justice (feud) or the pursuit of power and the promotion of political agendas (war).

In small, family-level, egalitarian societies, aggression is typically personal and may or may not escalate to revenge killing. When a killer is killed, self-redress homicide or capital punishment is the socially sanctioned means of achieving justice. Killing a recidivist murderer is usually limited to the perpetrator of a prior homicide, i.e., a person whose criminal responsibility has been well established. The object of such 'eye-for-an-eye' actions may also include deaths attributed to conjurers, shamans, sorcerers, witches, or anyone who is believed to have killed their victims by 'black magic' or other forms of supernatural power (Fry, 2006; Kelly, 2013).

Until humans became relatively sedentary and began to domesticate animals and plants, the world was populated exclusively by hunter-gatherers, and virtually all of them lived in small, egalitarian, family groups, that is, societies without social classes, hierarchies, ranking, or segmentation. In other words, they lacked clans, lineages, or sodalities. Skeletal data are rare prior to about 25 000 years ago, but the available bioarchaeological evidence suggests that foragers lived a hazardous lifestyle, one involving close encounters with large game, as well as interpersonal violence, but there is a general lack of evidence for organized feuding or endemic warfare (Kelly, 2013). Living in widely dispersed bands with few material possessions to fight over, cannibalism, hunting accidents, predation, and self-redress homicides, rather than revenge killings or warfare, may account for virtually all skeletal traumas during much of human prehistory prior to about 12 000 years ago. A case in point is Kennewick Man, a 9300-year-old Paleo-Indian hunter-gatherer, who suffered multiple violent traumas, including old wounds that had healed – a still-embedded stone spear point in the hip, depression fractures on the skull, a broken rib, and massive blunt trauma to the chest. He also had an infected head injury and a fractured shoulder blade, neither of which shows the effects of healing (Chatters, 2004). Healed wounds, such as these, may reflect interpersonal violence rather than feuding or warfare in which death is the objective.

In a recent overview of European and Near Eastern conflict and war (Ferguson, 2013), the European Paleolithic revealed little evidence of violent injury – it was not until the subsequent Mesolithic period that several instances of multiple deaths are documented, suggesting the beginning of recognizable intercommunity conflict, such as feuding. Ferguson notes that Near Eastern hunter-gatherers exhibited some personal violence, but the shift to widespread intercommunity violence was not evident throughout the Near East until the Early Bronze age when war arrived in an abrupt and dramatic transition. While modern, egalitarian hunter-gatherers are not our 'contemporary ancestors,' nor exemplars of our remote past, they do provide important material correlates of how cultures maintain peace and limit aggression, conflict, and violence, and as such guide archaeological thinking about the ways in which our ancestors engaged in conflict and violence and promoted cooperation and peace.

Tribes, Feuds, and Kin-Militias

Conflict and violence in small-scale nonegalitarian sedentary societies is based on a form of justice pursued through feuding based on social substitution – that any member of the murderer's social group may be attacked and killed as a substitute for the miscreant (Kelly, 2000). But generally it is the perpetrator or a close relative who must pay the price for the crime. Feuds are carried out by small, informal, and temporary armed groups organized as kin-militia who pursue justice and retribution. Feuding is characterized by "fighting in pursuit of individual or family ends rather than community or societal ends" (Carneiro, 1994: 6), and may result in revenge raids where kinship ties outweigh personal or political allegiance. In such situations of reciprocal violence, a "grudge precipitates retaliation, which in its turn becomes another grudge that ignites counter retaliation, and so on" (Reyna, 1994: 38). The social mechanisms for cooperation and peace may not be entirely effective to squash lingering or smoldering feelings of injustice, especially when the individual or kin group demands equity and revenge to assuage the corporate sense of honor.

Unlike warfare, feuds are characterized by outbursts of mutual hostility and violent assaults that are usually limited to one or two killings at a time, with fighting most often involving brawls, raids, and less often small-scale battles (Fry, 2006: 101). These vendettas, often fueled by the sense of a sacred familial responsibility or social duty, might entail a long-running cycle of resentment and hostilities between the aggrieved parties, as there are no clear or necessary political objectives beyond the maintenance of individual or family honor. The amount of pressure brought to bear on feuding parties by their own groups to end an ongoing dispute increases in proportion to the necessity of cooperation between the two factions (Boehm, 1987). For example, the Kapsiki/Higi, a tribal people who live in the rugged Mandara mountain range that separates Nigeria from Cameron, engage in duels, feuds, and staff fights brought about by accusations of theft, jealousy over

women, quarrels concerning land, and prior homicides. Battles and raids are led by a small militia consisting of a war leader, warriors, and distinguished warriors (Otterbein, 1994).

In feuding, related kin groups typically operate under weak chains of command, having only rudimentary powers for conquering or dispersing their enemies. Although organized violence is more effective than that found in bands, it is still relatively harmless when compared to the violence of centralized polities, consisting mainly of brawls, raids, and rarely battles. Thus, feuding can be seen as a judicial mechanism in which aggrieved kin groups seek justice through social substitution based on resolving personal grudges by "evanescent congeries of kin and allies thrown together for one or two operations" (Reyna, 1994: 42).

Raids operationalize the demands of feuding and are culturally sanctioned, often elevating the status of the successful individual to that of warrior, a status not found in egalitarian hunting and gathering societies. Feuding typically entails armed combat between localized kin groups within a political community (Otterbein, 1994: xix–xx). Unlike egalitarian foragers who are dispersed and mobile, and whose band membership is fluid, tribal-level, nonegalitarian hunter-gatherers and horticulturists are often sedentary peoples, characterized by well-defined territories and hierarchical social segments, such as clans, lineages, sodalities, and villages. Violence arises among nonegalitarian hunter-gatherers when mobility becomes less of an option due to high population density (Kelly, 2013: 165). With residential movement increasingly limited, available habitation locales become limited, scarce, and much sought-after, even to the point of being fought over, sometimes erupting into periodic, all-out confrontations. Among pre-Columbian southern California hunter-gatherers, for instance, conflict dramatically increased based on the frequency of projectile injuries from about 1500–600 years ago, perhaps precipitated by subsistence stress exacerbated by a growing population size and multiple droughts during the Medieval climatic warming (Lambert, 2007).

Key archaeological evidence for intergroup feuding, as opposed to self-redress homicides, includes human bone modification, mass burials of individuals with embedded projectile points, perimortem mutilation associated with trophy-taking, and skeletal trauma exhibiting broken and fractured bones. Modified human bones as grave accompaniments are frequently evidence of warrior prestige conferred by successful revenge attacks that become trophy-taking raids. Trophy-taking escalates among nonegalitarian hunter-gatherers and tribal societies as warrior status takes center stage and human body parts become a social currency in 'war' rituals and for social advancement. For example, Late Archaic hunter-gatherers of the lower Tennessee Valley of eastern North America adopted a feuding style of conflict resolution between about 7000 and 3000 years ago (Anderson, 2002; Dye, 2009). Graves contained modified human remains as trophies in the form of skull cap bowls and gorgets, carved fibulae and radius awls/pins, and modified and cut tibia and femur shafts (Smith, 1997).

The initial rise of tribal societies throughout the world witnessed increased violence based on kin-based raiding although many examples of skeletal trauma undoubtedly resulted from interpersonal violence due to murders resolved by self-redress homicide. In a feuding style of conflict resolution, victims of violence begin to appear with regularity in the archaeological record, as evidenced by embedded spear points, mass graves, overkill (inflicting greater injury than would be necessary to kill someone), pin-cushioning (leaving a large number of arrows or spears in a body), and trophy-taking behaviors. There is abundant evidence substantiating archaeological claims for feuding as opposed to self-redress homicide or warfare, especially in contexts where large samples of human skeletal remains are available, suggesting that blood feuds were the violent outcome of individual and kin group personal grudges.

Tribal alliance formation and conflict resolution would have been achieved through various ameliorative practices as recorded in the archaeological record, especially adoptions, feasting, and reparation payments that utilized symbolic weaponry and tokens of exchange and wealth that circulated as gift items. A case in point is the Hopewell exchange system, which consisted of many diverse communities in eastern North America that interacted with one another between approximately 2200 and 1600 years ago. In addition to a complex ritual landscape, Hopewell long-distance exchange networks dampened the pursuit of vengeance, enhanced individual status, and promoted alliances. Exotic materials such as copper from the Great Lakes, marine shell from the Atlantic and Gulf Coasts, mica from the southern Appalachians, and obsidian from Wyoming, served to establish territorial alliances and ritual mechanisms that mediated intergroup disputes. Such articles were widely dispersed among tribal groups, in part as blood payments employed in exchange systems whose underlying purpose resulted from conflict resolution associated with a feuding style of justice seeking. For example, in the American Midwest during the Colonial period, death compensation payments resulting from intertribal murders 'covered the dead' and reestablished peaceful relations and social harmony (White, 1991: 77–79).

The appearance in the archaeological record of combat iconography, symbolic weaponry, and trophy-taking may be early hall-marks of a feuding style of violence fomented by kin-militias. The revenge feud is so basic to human conflict and justice seeking, especially when efforts at peace fail, that they are still practiced in many areas of the world where local law enforcement is weak or ignored. For example, in modern Montenegro in the European Balkans, blood revenge continues to engender an unspoken social obligation to seek retaliatory revenge to salvage one's honor as a result of moral or social disrespect, a prior murder, or a sense of public humiliation (Boehm, 1987).

War and the Rise of Chiefly Militias, Aristocratic Armies, and Industrial Armed Forces

War is ultimately about authoritative power – authority legitimized by military force and political rules – and the individuals who through social organizations control and deploy it (Mann, 1986). Through war, individuals or governments seek to increase political power or to maintain the status quo while undermining the political power of an opponent. With the evolution of centralized polities and their emerging political

and social hierarchies, new ways of structuring violence gave rise to the organization of lethal military forces. War involves the entire social group "organized as political communities, and – intentionally or unintentionally – its outcomes affect the balance of power between such social groups and communities" (Wolf, 1987: 129). While warfare may temporarily exist among less centralized societies, it is among regional polities such as chiefdoms and states that warfare pursues 'national' policies by inflicting unprecedented lethal aggression against one's enemies. War thus entails relatively impersonal violence for political motives between autonomous communities for political power (Fry, 2006: 140). The scale of warfare runs the gamut from occasional expedient chiefly battles to the campaigns of industrial nation-states.

Chiefdoms and Chiefly Militias

Warfare among chiefdoms is based on a corporate organization that includes a chief's retainers who form a council and the militias they call up from within the polity and neighboring, allied polities (Reyna, 1994: 43–44). Chiefly militia units might include warrior contingents from the low hundreds to several thousands (Carneiro, 1990) and were capable of superior tactics over tribal kin-militias because of improvements in military structure, which enabled chiefs as leaders to issue orders down through the chain of command. Religious cults further strengthened a chief's military authority by aligning a culture hero's interests with the ruling elite's political agenda. War councils, held to discuss tactics and strategies, depended on advice from experienced warriors, counsel from priests, and intelligence from spies. Chiefly military hierarchies possessed rules that underwrote chains of command, which in turn provided the leadership necessary to maneuver formations that concentrated militias at strategic points of attack and created the element of surprise. Chiefs had the capability to commit their forces in restricted campaigns with clear political objectives that could result in great slaughter, and to construct durable, substantial fortifications that attracted followers by providing protection and allowed horticultural production to be intensified.

Chiefly warfare was chronic in frequency and regularity because violence became an instrument of chiefly policy (Earle, 1997), with political objectives often including grudge resolutions arising out of elite conduct concerning political posturing, public affairs, and resource acquisition and intensification. Through military organization, force could also be deployed to acquire material goods as forms of tribute and to appropriate social labor. With the rise of chiefly militias violence could be deployed to "create, maintain, and transform social relations" (Reyna, 1994: 46), thus providing chiefs with an organizational apparatus to aggregate polities for their benefit and to construct massive fortifications. For example, the Colla of southern Peru's Titicaca basin (*c* AD 1000–1450), comprised of a series of weakly centralized confederacies, controlled the plains of the northern basin until about 1450, when they were conquered by the expanding Inca Empire. The Colla moved away from their rich farmlands during a time of extended drought, political fragmentation, and intense inter- and intraethnic conflict. They settled on defensible ridges and hilltops, sometimes gathering in large fortified towns. The extraordinary investment in their hillforts indicates a high level of concern with warfare that resulted in a balkanized political landscape prone to repeated conflict. Warfare at this time was unmatched at any other time in the archaeological sequence of the Titicaca basin, intensifying in the fourteenth century as power-hungry warlords constructed durable fortifications and engaged in cycles of revenge that embroiled the Colla in periodic wars (Arkush, 2011: 212).

The archaeological and ethnohistoric documentation of New Zealand Maori warfare also presents an instructive case for the evolution of chiefly conflict and war. There, a pattern of revenge and status rivalry devolved to a state of endemic and entrenched war over land, other resources, and politics. The construction of pa (fort) was an economic and political task undertaken by leaders who organized and financed fortification systems through negotiations with their followers, and in the process furthered their own political ambitions. While Maori pa made conquest much more difficult, it also enabled ambitious leaders to attract followers through the promise of enhanced security and also undermined further political centralization (Allen, 2006).

Archaic States and Aristocratic Armies

As archaic states arose between 5 and 3000 years ago in many areas of the world, aristocracies emerged that garnered unprecedented military and political power (Sinopoli, 1994). The nobility, through the deployment of violent force, routinely battled their neighbors. Unlike chiefdoms, with their chiefly militias, early states organized professional soldiers into armies headed by nobles who controlled the command structure, dominated critical weaponry, and welded the hierarchical organization into a coordinated and efficient fighting force. Regional campaigning, organized as a coordinated series of battles, was a perpetual practice of aristocratic armies and often resulted in recurring cycles of empire building and destruction. Through vastly increased lethality and organization, aristocratic armies possessed the means of violent force, which conferred greater aggregative powers than had previously existed in the history of the world (Reyna, 1994).

Aristocratic armies, composed of specialized combat teams that mutually supported one another on the battlefield, coordinated their strategies and tactics based on various maneuvers and weapon types. Once the logistical problems of planning and carrying out the movement and maintenance of military forces that plagued chiefdoms were overcome, armies became permanent fixtures on the political landscape, attempting to annihilate their enemies and to hold conquered lands through force of arms to extract revenues and tribute for the state. Appropriated peasant labor served as a form of taxation and tribute that underwrote the military organization and shored up the stratified class structure.

Grudges among aristocratic elites often prompted motivations for war in early states, with antipathies and hatreds among rulers stemming from political machinations. For example, William I, Count of Normandy, considered his genealogy as privileging his claim to the English throne. William thought his claim stronger than that of the current monarch, the Anglo-Saxon Harold Godwinson, the Earl of Wessex, a member of the most powerful family in England.

William's first cousin, the childless Edward the Confessor, had named Harold as successor to the throne, even though Edward had earlier promised the kingship to William. To further complicate matters, Edward had previously sworn allegiance to William. Furious at the turn of events, William amassed a large army and fleet, invaded England, and defeated and killed Harold at the Battle of Hastings. William went on to sack the English shires and was crowned king in London on Christmas Day 1066, becoming William the Conqueror of all England. William's claim to the highest office in England, based on his aristocratic genealogy, is an example of a 'noble grudge-of-state.' Much of the conflict and war in archaic states can be traced to aristocratic machinations, with the regional campaigns conforming to the logics of aristocratic economic and political interests (Reyna, 1994).

Nation-States and Industrial Armed Forces

The armies of nation-states appeared around the beginning of the nineteenth century, creating industrial fighting forces that fomented previously unimaginable lethality, unparalleled violence, and unprecedented devastation. Replacing military leaders whose offices were based on claims to aristocratic status with leaders who possessed professional abilities in management and technology, armies assumed technical expertise and created sophisticated war machines. Modern wars are often fought for profit, as a component of the military–industrial complex, driven by escalating arms races and the needs of large, standing military forces that must be maintained through taxation. Military enemies of the nation-state are potential foes who stand in the way of national aims and strategic interests. While chiefdoms might field chiefly militias of several hundred warriors and archaic states could deploy thousands of soldiers, the industrial nation-state has the capacity to field armies of millions. In some battles, which might extend for months, massive causalities could be incurred. For example, in World War I two roughly contemporary battles in 1916 resulted in over 2.5 million causalities. The Brusilov Offensive from 21 February to 18 December, resulted in 1.6 million causalities (Dowling, 2008), while in the Battle of the Somme, from 1 July to 18 November, more than 1 million people were wounded or killed (Hart, 2010).

The practices of ancient and modern armies are being studied by battlefield archaeologists (Geier et al., 2010; Scott and McFeaters, 2011), who investigate the organization and management of war at sites that played important roles in military events, including not only battlefields and combat zones, but also arsenals; camps; forts; supply depots; and prisoner-of-war, internment, and concentration camps. Battlefield archaeology holds that conflict and military sites reveal the cultural behaviors and practices of combatants and these practices can be studied through archaeological methods, techniques, and theory.

The Archaeology of Conflict and War

The archaeology of conflict and war has matured over the past several decades, with greater attention being paid to the role of aggression, violence, and war, as well as cooperation and peace (i.e., Dye, 2009; Fry, 2013). The ability of archaeologists to unravel the nature of intersociety aggression and conflict through the study of past human behavior and its material culture has improved considerably due to new techniques, methodologies, and theories. For example, the use of metal detectors has increasingly become an important component of conflict archaeology, while geophysical prospection has made it possible to virtually 'see' beneath the soil, revealing crucial information about battle grounds and durable fortification systems (Scott and McFeaters, 2011). Greater attention is also being paid to military science (Allen, 2007), as well as the ways in which fortifications may constrain warfare, as well as being a reflection of it (Arkush, 2011). Recent perspectives on the role of trophy-taking in feuding and war place such activities within a cultural context, removing interpretations that are based on demeaning and ethnocentrism stereotypes (Chacon and Dye, 2007). New developments in the archaeological study of conflict and war in the coming decades will embrace the ethics of reporting on violence and warfare (Chacon and Mendoza, 2012), as well as calling greater attention to the investigation of aggression and conflict and how violence developed in tandem with cooperation in the evolution of human society.

Archaeological studies of intersocietal violence are based not only on material culture, but also on studies of ethnographically and historically documented ancient and modern cultures. Archaeologists contend that patterns of conflict are not only recoverable in the archaeological record, but that archaeology is critical for answering questions concerning patterns of conflict and war in the remote past as well as more recent times. The archaeological record is clear – when feuding and war appear among past societies, the archaeological evidence is also present in the form of combat iconography, durable fortifications, settlement patterns, skeletal trauma, and specialized weaponry.

In virtually every society some degree of fighting or violence takes place, in spite of institutions that maintain positive relations, promote cooperation, and quell violence. But as shown by archaeological examples from throughout the world, sociopolitical complexity and lethal aggression are intertwined in complex, but patterned ways; thus, there is a strong correlation between conflict and social complexity (Kelly, 2000). Based on archaeological research, what is clear is that the degree and nature of social integration profoundly influences how conflict and cooperation are structured, underscoring the idea that violence is largely a behavioral choice. People engage in war when it is in their interests to do so, but war is not chosen lightly, as it is costly, dangerous, and lethal (Ferguson, 2013).

A growing body of archaeological data testifies to the presence of prehistoric violence around the world, dispelling the myth of a peaceful human past (Arkush and Allen, 2006; Chacon and Mendoza, 2007a,b; Dye, 2009; Keeley, 1996; LeBlanc and Register, 2003). The evidence of violence, however, is varied in both nature and scale, suggesting that neither war nor peace has been the 'natural' state of humankind. Instead, both are products of specific social circumstances, histories, and practices (Fry, 2013). The archaeology of

conflict and war is part and parcel of human culture, and as such can only be understood from the perspective of the political and social contexts in which intersocietal violence has evolved. Conflict, violence, and war are therefore functions of particular forms of political and social organizations, and the specific modes of sociocultural conditions and historical development have specific expressions of aggression and conflict (Kelly, 2000).

In addition to ritualized violence such as competitive sports and rough and tumble play, and a rugged, outdoor lifestyle, three basic modes of culturally sanctioned conflict may be defined for human societies: self-redress homicide, feud, and war (Dye, 2009; Fry, 2006; Kelly, 2000; Reyna, 2006). Each mode results in a distinctive archaeological signature as a result of the sociopolitical contexts of aggression and conflict. First, self-redress or revenge homicide is characteristic of egalitarian hunting and gathering bands, where social segments are weakly developed or lacking altogether. Self-redress homicide takes place when a killer is killed – not by the social group as a whole, but by one's kin as a form of justice sanctioned by the social unit. Egalitarian forgers typically lack feuding or warfare. Second, feuds and kin-militia raids are characteristic of tribes; in many cases these are societies in which aggrieved parties seek personal retaliatory justice either by killing the accused or the close kin of the accused through a sense of socially authorized revenge. On occasion feuding behavior may escalate into warfare. Finally, chiefdoms and states engage in warfare, defined as armed conflict with the goal of upsetting the balance of power between autonomous political communities. Each of these modes is a reminder that as society becomes increasingly complex, so too does its mode of aggression and violence. Of course, self-redress homicides and feuds do not occur in lockstep with the scale of political organization. They are pursued in virtually all societies, as different forms of violence can occur in varying sociopolitical settings. The point here is to emphasize predominant modes or trends in intercommunity conflict and violence and their relationship with the way in which society is organized.

The key to understanding conflict and war is to ask whether cooperation is a losing option or whether violence is the only viable course of action (Fry, 2006, 2013). The important question is: What is the nature of violence, and under what conditions do levels of violence vary? The intensity and level of warfare increases with the scale of cultural complexity and the degree society is integrated. Organized violence throughout the world underwent a series of major transformations, from the absence of warfare prior to about 5000 years ago to the creation of state-level armies in the nineteenth century. Violence among simple, unsegmented hunter-gatherers would have been restricted to self-redress homicides. As simple foraging societies began to develop social segmentation, feuding became more prevalent throughout the world. In time, chiefly warfare incorporated formal, hierarchical institutions and inherited offices as part of elite aggrandizement that escalated organized violence. With its great time depth and global perspective, archaeology offers a distinct and unique contribution to the study of human conflict and warfare.

Abstract

The archaeology of war is a late 'discovery' of the mid-1990s, but since then advances have been made in understanding the scale and roles of warfare in the early history of mankind. Warfare understood as violent encounter with the other probably occurred from the earliest hominids and has accompanied human societies ever since. There is ample evidence of this in terms of skeletal traumata, material culture, weapons, war-related ritual finds, fighting technologies, fortifications, and martial iconographies. New inquiries into these data sets testify that war was often present but rarely grew endemic. Rather the scale of warfare varied with historical circumstances tending to become more comprehensive and even habitual in times of radical social change. Peace was usually part of the picture too. This overall rhythm may suggest that warfare is deeply embedded in a cultural nexus rather than being a question of biology, evolution, or genetics. If not precisely a driver in history, warfare seems nevertheless often situated within the web of causes and effects of social change. The emergence of weaponry made specifically for war is overall contemporaneous with the first institutionalizations of warfare. This is a late phenomenon in the history of mankind dating to between the fifth- and third-millennia BCE from whence the warrior was commemorated in rituals as a figure of glory, beauty, and valor. Besides, genuine weapons and institutions of warfare concur widely with the implementation of more cogent forms of sociopolitical order with stronger leadership and explicit social divisions.

> So the possession of costly bronze daggers, swords, and rapiers consolidated the positions of war-chiefs and conquering aristocracies as did the knights's armour in the Middle Ages.
>
> Childe, 1941.

Archaeology is a science that provides knowledge of the past while relying on the material record of human interaction from very remote periods of early hominids to the recent history of modern humans all over the world. This record can be processed analytically to form complex data sets capable of delivering detailed knowledge of past human life worlds. Besides, it permits the analytical spotlight to be directed toward sociocultural encounters between human actors and the material domain of objects, buildings, resources, and environments. The actual interactions and organizations can be reconstructed as well as the ideological constructs based upon them. Because of the material nature of its sources, archaeology has the capacity to scrutinize concrete remnants of interactions as well as to track long-term historical trends and turning points. The discipline of archaeology therefore also has a huge potential to situate war, warfare, and the adjacent identities within a wider field of historical situations and trajectories.

Nevertheless, warfare as subject has been absent, or marginal, to scholarly inquiries except for the past couple of decades. Albeit there are exceptions as vividly exemplified in the opening quote by one of archaeology's founding fathers V.G. Childe, the 'discovery' of prehistoric warfare came as late as the mid-1990s triggered by the publication of L. Keeley's seminal book *War before Civilization: The Myth of the Peaceful Savage*. This event marked the beginning of a new scholarly awareness of the violent side of prehistoric societies which is much more in accord with the archaeological data, as shall be proposed below. The archaeology of periods with written records notably has a longer tradition for studying matters of war taking inspiration from military philosophy and military history. Stimulated by especially social anthropology and sociology, prehistoric archaeology constitutes the core of the current genre of 'Archaeology of War,' and from this broad category new academic fields are presently developing, such as the archaeology of battlefields and war commemorative studies.

The past 25 years have seen a huge body of publications often adhering to the Hobbesian thought that human beginnings were violent and chaotic. One might say that while the past in preceding studies was thought to be overall peaceful (doves, noble peaceful savage) interpretations after 1996 quite often take the opposite stance of a chronic state of war (hawks, fierce bellicose savage). While current archaeology and anthropology can sustain that warfare was very often present and sometimes grew habitual, it also proposes that warfare was rarely endemic in the Hobbesian sense of everybody's war against everybody. Warfare is not usually a form of interaction people engage in because they cannot be without it. Rather people in nonstate settings wage war because it is a less risky strategy than is peace inasmuch as allies can never be fully trusted. The archaeology of most periods and places convey a variable picture of both peaceful moments and different varieties and scales of warfare, which sometimes display an unspeakable cruelty that fully matches atrocities committed in our own time. In recent publications, warfare furthermore tends to be subjected to evolutionary schemes with the violence either becoming more, or less, frequent and lethal with time.

This brings up the question of war as a potential driver in history. Following R.L. Carneiro's seminal anthropological article from 1970, it is at times taken for granted that warfare expedites social change, and even produces state formations, as in the recent work of F. Fukuyama. By comparison, archaeology seems to point in the direction that warfare was often placed somewhere in the web of causes and effects of radical social

change. War can in some situations perhaps be singled out as a driver behind new social realities; however, the pathway was probably most often more indirect in that prolonged periods of warfare made existing hierarchies weak and promoted new social platforms from which new identities could rise.

Archaeology clearly has the potential to provide knowledge about the evolutionary position of warfare in a deep historical perspective, warfare's possible role as primary mover, and other topical issues, but it is a scientific venture only just begun. Insights will be affected by how narrowly or broadly warfare is defined at the outset. War and warfare are sometimes narrowly defined as the violent activities within state societies, but will here be widened considerably to encompass all forms of armed violent conflict between social units. While the term 'war' describes recurring situations of armed conflict, 'warfare' refers to the concrete waging war, but a degree of synonymy between the two must be accepted.

What Is Warfare?

Warfare may be subdivided into a number of overlapping categories varying from feuding among fraternal interest groups and raiding into foreign territory to large-scale military actions and place-bound battles; its precise form, scale, frequency, and content dependent on the specific societal and cultural setting. It makes good sense to understand warfare as basically cultural encounter, both internally in a group (intracultural) as well as externally toward other groups (intercultural), and not reducible to being merely a particular form of violent collective social action. Rather, warfare is interaction, both violent and nonviolent by character and comprising phases of persuasion, agreement, planning, and cooperation in addition to the violent confrontations, and very often postwar rituals. If warfare turns inward in the group (~civil war; feuding) this has in effect already been fractioned since warfare always seems to emerge from bounded social units. Warfare is waged against outsiders and violent conflict as such tends to rise from the construction of exclusionist identities, basically a question of us against them. Sociologically and historically, armed conflict both reinforces existing collectivities and has a tendency to produce new ones.

As a suitable entrance to archaeological inquiries, warfare can furthermore be comprehended as a *durée* of intentional activities; a continued flow of interactions, which ultimately imply violence and which produce unintentional consequences that are again acted upon. As a form of social interaction warfare cannot be meaningfully separated from the rules, norms, and resources of society as such. Besides, warfare often connects to rituals and other social activities, which may in sum be regarded more as a continuum of interaction than as separate practices. Not all conflicts end up in violent confrontation, but are often solved by nonviolent means, which is an important point to make.

Violence is at the very core of warfare, but is also a comprehensive concept comprising, in addition to warfare, for example, interpersonal aggression like homicide, intra-family hostilities and wife beating, forceful kinds of sport, human sacrifice, and juridical or political punishments such as torture, maiming, and death penalty. It may be difficult to distinguish clearly between these forms of violence in every case based on purely archaeological grounds. Moreover, the boundary between them can be quite subtle, and ethnography suggests that a high occurrence of interpersonal and ritualized violence other than strictly warfare quite often coincides with periods of intensified warfare. The term 'war-related violence' can often serve as a preliminary classification or acceptable compromise when archaeological data do not allow a precise categorization of the kind of violence involved.

The fighters themselves, the warriors and their leaders, are the chief actors of warfare whose roles rely on a considerable amount of movements across landscapes and at the places of fighting. Warriors are the special agents, even in some cases literally professionals, who have been trained in the bodily material techniques of warfare. War and warfare invariably produce death, suffering, and trauma, and warriorhood can therefore be defined as an identity, or profession, that domesticates the associated fear through a learnt scheme of skills and techniques, stored in brain, body, and material culture in complex not divorceable ways.

The term 'warriorhood' is another key to understanding warfare in the past: it can be defined as an individualized social identity closely connected to military actions, but also motivated by myth and ideologies of men, glory, and war. Because it requires a physical risk and offers a chance to display individual courage and bravery – warfare is in many societies acknowledged as a route to social success in that it may generate social capital suitable to invest in social strategies of power. Males may from early boyhood be socialized into the warrior role, as in many parts of colonial Africa, Melanesia, Australia, and South America. Here warfare was not necessarily conducted from firm military units, but able males were momentarily committed to the task and engaged in fighting on ad hoc basis. When, however, warriors organize in institutions of war, so-called warbands, they do it in three different ways with access to the 'club' based on principles of age (age grades) or social prestige and personal status, and in a number of instances also distinctions of rank and class. In this latter case recruitment happens from the dominant societal level or followers are more broadly appointed by a warleader of high social standing. The aristocratic warband with special codes of conduct (*Gefolgschaft*) is described in numerous ethnohistorical cases of chiefdoms and archaic states as well as in the ancient written sources from Tacitus' *Germania* to the epic classics of the Rigveda, Homer, and Beowulf; these are all rooted in Bronze Age and Iron Age worlds and therefore important for the understanding of warfare from the third and second-millennia BCE onward.

Other agents and groups than strictly warriors may be influential in warfare, such as victors, collaborators, allies, enemies, victims, civilians, and ritual specialists. Such groups may interact with each other in a flow of interactions that also incorporate material objects and environments in ways that impact society. Furthermore, warfare implies targeted use of weapons, which may nevertheless have functions in other social domains than war.

In the following the main categories of archaeological sources to warfare will be centrepieces in discussing the essences, scales, and organizations of war, weighing its material components and main actors as well as the often considerable

ideological input. Emphasis will be on war before history. Warfare as defined and outlined above permits us to resolve that war-related violence has occurred occasionally from the first human beginnings and throughout history and has periodically taken a predominant position in everyday life. The (co)emergence of institutionalized warriorhood and weapons made solely for war constitutes important watersheds in the history of warfare and ancient society.

Weaponry

Weaponry divides arbitrarily into implements with a potential for war and real weapons intended for offensive and/or defensive purposes. Bows and arrows, points, axe blades, knives, and daggers, made of various organic or nonorganic materials, belong to the first category. In fact, almost any object can find uses as weapon if need be, and this was certainly the case from the earliest times and throughout the history of mankind. The second category comprises mainly swords, spearheads, shields, and body armor, but also maceheads and battle-axes. These objects were definitely produced with warfare in mind using selected materials to effectuate this purpose. Weaponry for war is a late phenomenon measured on the background of millennia of human history. In Eurasia battle-axes and maceheads began to appear only after the introduction of farming, and particularly in Europe more systematic production and uses of these weapons are in particular attached to the so-called Corded Ware period dating to the onset and first centuries of the third-millennium BCE and which seem to link up with spread of Indo-European languages, wheeled vehicles, and probably horses from a homeland in the north Kazakh steppes. The early third-millennium BCE also brings us the first clear evidence of warband institutions: Organized frames for warfare and warriorhood.

Weapons for war typically occur in burials and other ritual contexts and they constitute a large category of finds from later prehistory and onward, hence testifying to the presence of warfare within a broader social domain. The appearance of these first weapons – made unequivocally for waging war and often made in copper, bronze, or spectacularly colored stone – in many places coincides with the emergence of marked social distinctions with cogent forms of leadership and discrete organizations of war. Throughout, the distinction between would-be weapons made in any material at hand, weapons such as bow/arrow with other uses, and genuine weapons made in special materials seems concurrent with social distinctions in society as such and with distinctions in warfare between war leaders, high-ranking warriors, and common fighters. With the mature Bronze Age from 1700 BCE, or somewhat earlier in some regions, this picture becomes particularly distinct sustained by the innovations of spearheads and swords and adjacent novel techniques of fighting in the upper echelons of society. In the Final Neolithic (Copper Age) and particularly in the Bronze Age, the group of genuine weapons grew markedly in numbers and in technical and ornamental elaboration. This seems tied to the general inventiveness of these periods, but almost certainly also to reorganizations of institutions of war and new ideologies to support them. Although the presence of warrior clubs is rather strongly indicated from around 2800 BCE in temperate Europe, their more precise position, central or marginal, in the societal meshwork is unknown, but could have varied enormously in the period 3000–500 BCE. In the Bronze Age the warband seems to grow in importance and its internal organization to be based on hierarchical principles.

The above typology of weaponry roughly suggests that most weapons have potential uses outside warfare, notably hunting. Bone assemblages from Final Neolithic and Bronze Age settlements normally show little inclusion of wild animals, and it can thus be presumed that hunting in these periods, and most certainly in the Bronze Age, was more a matter of prestige than economic necessity for at least the privileged part of the population. The boundary between prestige hunter and warrior can be blurred, as famously illustrated by the lion-hunt dagger from Shaft Grave IV at Mycenae. Dating to *c.*1600–1500 BCE, it shows warfare against the lion. This is likely a metaphor for bravery in combat and for the princely warrior chieftain in early Mycenaean society. In the thirteenth-century BCE, this symbol was appropriated by the royal house of Mycenae as their 'coat of arms,' visualized so vividly by the Lion Gate to the citadel.

The multifunctionality, or ambiguity, of material culture in general implies that weapons cannot be reduced merely to tools of war. A series of other potential functions and meanings presents itself. Notably, weapons often maintain identities of gender, age, rank, or various other types of group identity like kinship, ethnicity, and profession. In European prehistory the cultural biographies of weaponry typically ended with a ritual deposition either in burials or in votive offerings. Such depositions may comprise one item or a combination of several items depending on cultural and social factors. From the Bronze Age of temperate Europe and in several similarly organized societies around the world numerous weapons exist; the sheer quantity being ample testimony to warfare as an option that could be acted upon and indeed to the presence of warriorhood as an identity feeding from bellicose interaction and from ideologies of war. Macro- and microwear analyses of swords and other weapons confirm that many have indeed been put to repeated and forceful use. It is often speculated that some of the most spectacular weaponry: shields, helmets, giant axes, and body armor – for reasons of construction – cannot have been very suitable for warfare, but again such splendid items likely had several social uses in addition to warfare. Such weapons may have had ritual functions in funerary games, religious performances, and/or were parade armor that should impress and scare. This may be supported by the pictorial slabs from the Kivik tomb in Scania from around 1500 BCE, rock-carving scenes from various places in the Eurasian Neolithic and metal ages, and by Patroklos' funeral games in Homer's *Iliad*. By contrast, a substantial series of other weapons exists that were surely meant to wound and kill other human beings: spears and arrows definitely belong here, as do the swords. Especially the swords are central to our understanding of the Bronze Age and later prehistory/history as they mediate tales of supreme, active, and symbolic warriorhood among privileged strata in society. However, albeit less prestigious, spears and in particular arrows were key weapons for attack and defense, as shown by their massive presence in the early battlefield of Tollense near Greifswald in north Germany dating to around 1200 BCE. Projectile points of flint, and later in metal, sitting

in situ in human bone constitute a frequent form of skeletal trauma and cause of death throughout later prehistory, especially from Neolithic farming communities in the ninth to eighth millennia BCE and onward.

The exquisite and highly specialized craftsmanship of many of these weapons of metal suggests organized warriorhood in warbands. It would also support the suggestion that such warrior institutions were recruited and organized internally according to hierarchical principles, and thus not unlike the system that can be deduced from the *Iliad*, from Tacitus' *Germania*, and from a large number of ethnographically studied cases. A material hierarchy of weapons arguably existed, which was differentially constituted in different periods; in the later Bronze Age from *c.*1200 to 700 BCE likely with metal-hilted swords and body armor in the top part, followed by organic-hilted swords, axes, spearheads and arching equipment lower down, and wooden clubs and similar items in the bottom part. Such hierarchies of weaponry may be suggested to reflect social divisions within warrior institutions.

Weapons can be highly individualized objects – swords usually are – and thus invested with personalized names and meanings while simultaneously mediating in variable measure gender, status, rank, kinship, ethnicity, profession, and so on. Weapons may have whole biographies and stories attached to them, which could have been invoked on special occasions. The famed boar's tusk helmet which Odysseus puts on for a nightly spying expedition is a case in point, which could very well generally apply when looking at the finest prehistoric weapons, such as the twin horned helmets of bronze (*c.*1100 BCE) found in a bog at Viksö in Denmark. Such particular weapons are perhaps likely to be inalienable possessions kept in the family as tokens of memory and inheritance or ritually exchanged with the gods in sacred places or with very particular ancestors in monumental tombs.

The potential multifunctionality of material culture thus implies that weapons cannot be reduced merely to being war implements, but became intertwined with other social uses, as also suggested by contextual evidence. Even the most frightening or deadly of weapons very often had alternative social functions outside the strict sphere of waging war. Albeit the spotlight has here been on weaponry and what it can tell about warfare and its organization it is equally true that countless archaeological data exist that inform about peaceful moments, domains, and times.

The cultural biographies of weapons typically ended with a ritual deposition either in burials or in votive offerings. Such depositions in later European prehistory comprised one item or a combination of several items depending on cultural and social factors. The archaeologist thus obtains intimate knowledge mostly of the concluding activities, the ritual death of things, which may have had several very active lives prior to the final deposition. These final destinations of weaponry, however, may still be able to deliver information about the living society, as outlined above and substantiated below.

Weaponry in Ritualized Contexts

Weapons and other objects were from early on systematically deposited in burials and at other ritual sites. This may have happened for a variety of overlapping reasons such as emotion, social ambition, social rivalry, and social identity, commemoration of persons and events of war, and to sustain cultural values and norms, including religion. Ritual actions such as funerals and offerings can be carried out routinely as the way things should be done or more deliberately as political announcement questioning or legitimizing existing relations of social power.

Numerous graves with weapons are known from different periods all over the world, but their direct or indirect relationship with warriorhood has only just begun to be studied. From the Final Neolithic in temperate Europe – the Corded Ware and Bell Beaker periods – good cases can be made of warrior identities and institutions although allowing for cultural variations. From the Bronze Age and Iron Age one can easily identify conspicuous individual graves with rich weaponry attached to mature males who may have been high-ranking warriors and warleaders, perhaps still actively engaged in war and/or this role was mainly effected on a symbolic level as heads of society. Females were not usually buried with weapons, albeit notable exceptions exist such as Scythian–Sarmatian interments, so-called Amazons, at the Don and Volga. Women's roles in warfare – to judge from written sources – probably were more active and motivating than often assumed.

It seems in many cases clear that the deceased were commemorated as warrior heroes by kin and community in the same way as warriors and soldiers have been celebrated and remembered in history and in our own time. Such presentations of the warrior's 'beauty,' glory, and valor are of course strongly ideologically colored, contrasting with the knowledge that the warrior is an identity also sustained by violence. Grooming items such as razors, combs, awls, and tweezers in addition to ornaments for dress and body very often accompany elaborate weaponry in so-called warrior burials; hence tallying with a cross-cultural inclination of warriors to be preoccupied with their bodily appearance. Presentations of warrior identities, as mediated in burials and other ritual context, are rooted in specific historical events but also in myths of war and its heroes. This also exemplifies ancient social strategies of distancing 'us' from 'them.'

The existence of elaborate weapons in metal dividing into several categories may suggest that warriors in later prehistory organized in warrior institutions. This is in general harmony with the funerary evidence, which is however also a very complex data source. Weapons and dress accessories in burials may be a direct statement of the roles played by the dead individual in life. Swords seem in the Bronze Age very rarely associated with child or female interments, and sword burials would then be generally suggestive of male warriorhood. Yet, weapons and dress accessories may additionally be used to make more general metaphoric statements and thus have a less direct bearing on the lived identities of the deceased. This may include symbolic warriorhood in the sense of an earlier warrior identity, heroic status or ambition, political authority, or high social rank; all of it possibly in combination. Likewise, weapons accompanying small male children and young adolescents, such as those found in some Corded Ware communities between 2800 and 2500 BCE are likely to be metaphors originating in warrior values rather than signs of active warriorhood.

The inhumation cemetery at Neckarsulm in Baden-Württemberg dating to *c.*1300 BCE, the early Urnfield period of the Late Bronze Age, is interesting in terms of active warriorhood. The majority of the 51 bodies turned out to be adult males of excellent health and physique, bow-legged as a consequence of horse-riding. Most had standard equipment of fine pottery and body accessories, but were surpassed materially by three sword graves situated close together at the eastern margin of the cemetery. Many burials contained several interments of males who apparently died on the same occasion. It is fairly clear from this case that the cemetery was devoted to warriors, that is, the buried males were active warriors who died and were buried companion wise, and finally that the warrior institution(s) had an internal ranking defined by those with swords and those without swords. A similar picture is conveyed by the numerous skeletons of young adult males at the above-mentioned site of Tollense, also containing horse skeletons, deposited under circumstances of battle and, fairly certainly also as a consequence of elaborate and violent postbattle rituals in the adjacent river.

As warfare is definable as a flow of social interactions, it needs to be somehow initiated and concluded, and rituals on individual and group level present themselves as obvious choices. Indeed, a large number of weapons are known from sacrificial deposits all over northern and central Europe, and far beyond these regions, and many of them have been retrieved from wetlands. This tradition of ritually depositing weapons and other valuables commenced in the first farming communities but grew over time in significance and likely became linked to beliefs in otherworldly existences. This specific ritual practice has been explained with reference to several overall purposes: rites of passage, gifts to the gods, and 'potlatches' to promote the importance of particular persons or social institutions and to legitimize or question power and authority. Among the Northwest Coast Indians, potlatch rituals only became truly elaborate when the Canadian government prohibited warfare, hence potlatch in this case became a substitute for waging war.

It seems that warfare in prehistoric Europe could have been systematically linked with postwar rituals finalizing armed conflict or they were somehow interwoven with ongoing warfare. This accords well with the above-mentioned Bronze Age site at Tollense from *c.*1200 BCE, which has yielded weapon offerings and numerous skeletons along the stretch of the river. The rich and elaborate war booty offerings of the north European Iron Age and the commemorative deposits of weapons from Greek shrines throughout Antiquity constitute similar cases of postwar rituals. Ancient authors from Tacitus to Pausanias amply describe such depository traditions relating to war, which even today is intertwined with rituals. While Neolithic depositions contain mainly implements with the potential for war, the more monofunctional weapons in depositions from the Bronze Age make an association with warfare more clear. War booty offerings, a generally accepted find category in Iron Age Europe sustained by written sources, could well be rooted in the Neolithic and especially the Bronze Age. While warfare cannot in general be understood as a ritual, it nearly always contains aspects of ritual. However, it is important to note that prehistory all over the world is replete with funerary and other ritual deposits containing mundane and extraordinary items with peaceful purposes.

Weapon Combinations and Technologies

Weapon combinations in wetland depositions and in cemeteries can, used with caution, inform about the internal organization of the warrior bands and of the equipment and fighting methods of the warrior. The warrior may not be interred with his full equipment but rather only those parts of the equipment that had a certain symbolic meaning or could be spared by the living. Particular weapons may have been curated, rather than deposited, for any number of reasons; perhaps kept to be used in future wars and in effect transmitted from father to son as insignia of rank and warrior status. Close combat armament predominates in burials and hoarded depositions, which should not let us conclude that archery was unimportant during fighting, as the continued occurrence of arrows of flint and metal shows. Special eye openers in this respect are constituted by settlement sites from the early Neolithic onward showing numerous arrowheads in the banks and ditches of the fortifications. Similar evidence comes from skeletal trauma showing marks from clubs as well as wounding and death by arrow shots.

The social presentation of the warrior in funerary contexts varied systematically through time indicating that fighting methods also changed. In the mid-third-millennium BCE, in temperate Europe and somewhat earlier toward south and east, the battle-axe-wielding warrior gave way to the dagger-carrying archer, who in the mid second millennium at the threshold to the Middle Bronze Age became a sword, axe, and spear fighter with several fine toilet articles to groom hair and body. Battle-axes and other axes of potential use in war were still available, as were less conspicuous and less prestigious weapons made of wood and other organic materials. It is quite possible that body armor and shields of organic materials were in use and forming part of the full panoply of the elite warrior. Wheeled horse-pulled vehicles were also present, perhaps from the onset of the third-millennium BCE but grew in significance in the metal ages. From around 1300 BCE, weapons look increasingly effective and standardized with elite warrior equipment consisting of the whole suite: sheet bronze armor, helmet, round shield, sword, and spear. This was in addition to toilet implements for grooming and now more often a four-wheeled cart or a two-wheeled chariot. The wheeled vehicle was to bring the war chieftain to and from battle and to present him as a superior being on social and religious occasions. This impressive assortment of weaponry shows developments over time with new highlights in the Iron Age with tribal confederations, archaic states, and finally the empire of Rome. All along this trajectory, there are regional variations in the techniques of fighting and the employed weapons, but the general development is similar.

Weapon technology is not unimportant for the outcome of war. Improvements have been known to escalate the degree and viciousness of warfare in numerous ethnographic cases. It is thus possible that innovations in the technology of war could have increased the speed of social change in prehistory. A comparison of weapons over time can give clues to significant

changes in weapon technology, understood as the quality of weapons and styles of fighting. The emergence of the sword around 1600 BCE in central and northern Europe is likely to have been such an important innovation with considerable social and symbolic effects in warlike as well as in more peaceful interactions inside society and between societies. Likewise, the introduction of horses for driving and riding, more systematically around 1200 BCE, would have changed conventional warfare as well as the whole social habitat, as documented, for instance, among the Grand Chaco Abipón in South America during the eighteenth century.

Fortifications

All over the world, regions with fortified settlements and villages can be singled out from the Neolithic onward and progressively more frequently, while tending to concentrate in periods of radical social transformation. This latter trend can be exemplified by the situation in central Europe and the Balkans between 1700 and 1500 BCE and again around and after 1200 BCE when large fortified strongholds with elaborate embankments were built at elevated points in the landscape. The Cyclopean strongholds at Mycenae, Tiryns, and other Mycenaean sites in Late Bronze Age Greece constitute very elaborate examples adhering to palace-organized archaic states. Likewise, hillforts occur throughout the Iron Age, as testified by the Celtic-tribal strongholds at Manching and at Alecia, which were conquered with difficulty by the Romans during the long military campaigns of Julius Caesar. In other regions, such as southern Scandinavia, unfortified settlements are the rule throughout prehistory. It seems that the presence or absence of fortified settlements cannot be used as evidence of war and peace, but need to be compared with other data. Absence of fortifications might be rooted in different sociocultural practices rather than peace as a prevalent state of affairs.

Fortifications are as multifunctional as other kinds of material culture. Fortified settlements are sometimes urban or protourban hubs for a limited region or even nodal points for superregional trade and crafts. These are peaceful activities denying daily life to have been intrinsically and chronically violent. At other times, fortifications are marginal phenomena placed at the boundaries of settled areas to scare off the enemy and to protect against intruders. In the latter case, they may not be permanently settled, or perhaps only with certain specialized personnel. Fortifications and territorial marking go well together, but distinct territoriality can exist without fortifications.

Skeletal Trauma

Traumata on skeletons can be caused by other forms of interpersonal violence than warfare, but are in many cases war related as suggested by ethnohistorical cases. Skeletal traumata are, in fact, relatively frequent in prehistory when it is taken into account that in some areas skeletons are not well preserved, that they are not routinely examined for marks of violence, and that much physical violence does not leave visible traces on the skeleton. A very long list of incidences of trauma exists, probably starting with early hominids and definitely continuing into the later periods of the Palaeolithic, Mesolithic, Neolithic, and so on, with a seemingly unbroken line to recent times. Bone projectile points embedded in the spine of a child (Homo Sapiens) occur as early as 30 000 BCE at Grimaldi in Italy and at *c.*18 000 BCE in the Nile Valley. Somewhat later, at the Mesolithic cemetery *c.*11 000 BCE at Gebel Sahaba, also in the Nile Valley, over 40% of the 50 individuals had died from arrow wounds.

Many cases cluster at the transition to the Neolithic when new forms of socioeconomies developed. These instances often occur in heavily ritualized contexts such as at Talheim, dating to *c.*5000 BCE, in Germany. Here 34 men, women, and children displaying perimortem trauma of exaggerated and highly brutal character had been buried with some form of structure in a mass grave. A similar and roughly contemporary case occurs at Herxheim, also in Germany, where an enclosured site with ditches contained the remains of numerous individuals. Some were disembodied in a ritualized manner as exemplified by decapitated skulls. Such abnormal mass graves with several injured individuals occur occasionally during later periods. Normal single interments with one injured individual also occur. In addition, multiple burials are known with a more normal pattern following prescribed 'normal' funerary rituals. A case in point is Eulau in central Germany, where a Corded Ware burial *c.*2600 BCE contained a man and a woman and two children, all with fractures in skulls, forearms, and hands and with arrowheads still sitting in the bones. These injuries had in all likelihood resulted from a hostile raid on a nearby settlement. Several similar cases are known distributed across time, as shown by, for example, the Crow Creek massacre in South Dakota with the remains of *c.*300 individuals dating to around 1325 CE. In general, injuries vary from projectile wounds to marks and cuts from weapons. Some wounds occur healed up, while other wounds were the cause of death.

Skeletal trauma is a valuable source of additional information when it comes to detecting warrior identities and to assess the frequency and scales of warfare. The considerable number of skeletons from *c.*1200 BCE at Tollense suggest that at this point in time large-scale warfare took place involving not only warbands but entire armies, perhaps consisting of individual warbands such as those described in Homer's *Iliad*. Postwar rituals involving further violence probably also took place at this and other Bronze Age sites.

Interestingly, looking particularly at European sources, there is a rather clear tendency for traumatized skeletons to cluster in turning points periods, such as at the transition to the Neolithic in many regions, the Corded Ware period commencing *c.*2800 BCE, and later on *c.*1700–1500 BCE and again *c.*1200 BCE. This pattern of clustering is interesting from the point of view of situating war within the causes and effects of radical sociocultural change. Moreover, it strongly sustains the cultural, rather than biological, essence of hostile encounters and war.

Iconographic Representations in Art and Rituals

Representations of martial arts, myth, and ideologies occur carved into rock, painted on walls and pottery, and printed into

vessels of ivory, stone, and metal. The date and social context vary enormously as do the geographical distribution and the representational media. Scandinavian Bronze Age rock carvings with scenes of ships, chariots, and warriors – among other themes – are clearly of mythical nature but surely also embedded in real historical events of long-distance maritime journeys, likely involving both trade and raids between 1600 and 500 BCE. Similar rock panels occur in Spain and northern Italy from the Neolithic and the Bronze Age, including fighting scenes with bows and arrows and tactical formations of advance and retreat among groups of warriors. Such carvings occasionally show prevalent weaponry of a given period.

Warlike presentations cluster in the representational art of Mycenaean Greece, where painted war scenes adorn the walls of central halls in the palaces while bellicose imagery, including siege scenes, warrior processions, and chariot driving are also depicted on stelae and vases. This is clearly the art of a martial elite. Scenes of warfare even occur in quite different social settings such as the fighting scenes carved on rock in southern Africa and attributable to hunter-gatherers of the San Bushmen. From quite another context and period, Classic Mayan wall paintings at Bonampak, Mexico, represent a battle between warriors as well as postwar rituals of beheading prisoners. Such representational art may be quite differently motivated, but is glued together by warfare as well as ideologies in support of these violent encounters. Martial representations from prehistory and onward should nevertheless be measured against the bulk of iconographies with peaceful scenes.

Concluding Reflections

A situation of reciprocity between data and theory has not yet emerged in archaeology because the study of warfare and violence is a late arrival of the past decades. Recent archaeological studies, in concert with recent trends in anthropology, permit the proposition that the level of warfare has varied with time and place. Even those more extreme situations where war has grown to become habitual are far removed from the Hobbes-inspired belief that human beginnings were intrinsically violent and chaotic. These new and emerging insights are likely connected to the combination of theoretical frameworks with cautiously produced data patterns in archaeology: so-called endemic, chronic, or total war has been exaggerated as a historical phenomenon. In addition, it is difficult to find empirical or theoretical support for the evolutionist hypothesis that warfare (or peace) gets more common through time. Similarly, it can be argued, based on present knowledge and hence with some weight, that war-related violence is mostly rooted in cultural logics rather than in biology, genetics, or evolution.

Conflict and War: Anthropological Aspects

Douglas P Fry, University of Alabama at Birmingham, Birmingham, AL, USA

Abstract

Although exceptions exist, war is usually differentiated from feuding within anthropology. A useful definition of war is specific enough to differentiate warfare from nonlethal brawls, single homicides, and kin-based feuding. Cross-cultural surveys show that a majority of societies practice warfare or feuding. At the same time, nonwarring societies also exist, sometimes as members of a nonwarring peace system. The occurrence of war and the reasons for warfare are correlated with the degree of social complexity, both archaeologically and ethnographically. Warfare has originated rather recently, within the last 10 000 years or so, in parallel with a worldwide shift away from a nomadic forager existence toward more complex social forms.

Introduction

> Each [Blackfoot] raiding party was hastily organized before departure and disbanded immediately after its return home …. Its members were motivated much less by tribal patriotism than by hope of personal gain – the economic security and social prestige that possession of a goodly number of horses would bring them.
>
> Ewers, 1967: 329

> Indeed, what the Gilyak called wars in ancient times were in fact nothing more than sporadic clan skirmishes motivated by vengeance or, even more frequently, were over women.
>
> Shternberg, 1933: 247

> Warfare among the Fijians was all-out and bloody, with no respect shown for sex or age. Women and children were killed ruthlessly and indiscriminately.
>
> Carneiro, 1990: 199

This article considers central questions regarding the anthropology of war. How is war defined? How does war differ from feud? How frequent are warfare and feuding cross-culturally? When did war originate, or in other words, how old is the institution of war? Do some kinds of human societies engage in more warfare than do others? What does anthropology suggest are the reasons for war?

Defining War

The way in which war is defined has direct relevance for answering questions about its origin, frequency, and distribution. Definitions of war vary from broad to narrow. If war is defined broadly as 'lethal aggression' (Low, 1993) without any specification, for example, that it pits one group against another, then homicides within or between groups could be counted as acts of warfare. Most scholars do not consider such behaviors to constitute warfare (Ferguson, 2013a,b; Sponsel, 1998).

Otterbein, who has been studying war, feuding, and other forms of violence since the 1960s, makes a distinction between feuding and war (Otterbein, 1968, 1970, 2004). He defines *feuding* as blood revenge that follows a homicide, a pattern of reciprocal killings, and he defines *war* as "armed combat between political communities" (Otterbein and Otterbein, 1965: 1470; Otterbein, 1970: 3). Like Otterbein, Boehm (1987: 221) distinguishes between feud and war: "Feuding is quite different from all-out warfare for several reasons: feuding is limited to one or two killings at a time; only one side takes the offensive at a time; and there is no necessary political objective beyond the maintenance of honor." Correspondingly, van der Dennen (1995: 93) writes: "in war – as contrasted with a feud – violence is relatively 'promiscuous': Anyone of the opposing community may be defined as an 'enemy' and thus be a potential victim. In a feud, the concept of enemy – and potential victim – is more restricted and selective: A particular member or members of a particular kinship group, family or clan."

On the other hand, Ember and Ember (1992: 172) lump together feud and warfare – a decision that leans toward maximizing the cross-cultural tally of warring societies – defining war as:

> … Socially organized armed combat between members of different territorial units (communities or aggregates of communities). In the ethnographic record, such combat usually involves groups on both sides, but a warfare event could involve the ambush of a single person of an 'enemy' group. Thus the phrase 'socially organized' means that there is a group of combatants on at least one of the 'sides.' This definition of warfare focuses on the behavior of groups, not on their presumed or reported motives for attacking and killing. Thus, we do not distinguish between warfare and feuding ('blood revenge').

Bowles (2009: 1294; see also Bowles and Gintis, 2011) recently has defined war so broadly as to not require any fatalities: Wars are "events in which coalitions of members of a group seek to inflict bodily harm on one or more members of another group." One problematic feature of this definition is that it is so inclusive that it could be applied to soccer hooliganism, riots, or banditry perpetrated by several persons. Most people do not consider such types of aggression to meet the definition of war. In contrast to overly inclusive definitions, Prosterman (1972) proposes a definition of war that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.96031-8

corresponds with common usage and that differentiates war from homicide and feud. For Prosterman (1972: 140), war is:

> A group activity, carried on by members of one community against members of another community, in which it is the primary purpose to inflict serious injury or death on multiple nonspecified members of that other community, or in which the primary purpose makes it highly likely that serious injury or death will be inflicted on multiple nonspecified members of that community in the accomplishment of that primary purpose.

Prosterman's definition clarifies that war is a group activity between communities directed against nonspecified members of the other community, which makes likely the killing of multiple people. Prosterman's (1972) definition of war is more detailed than Otterbein's (1970: 3) "armed combat between political communities," but these two definitions of war are in rough correspondence. Prosterman's definition of war also excludes individual homicides, even if committed by more than one person, in contrast to the definition used by Bowles (2009) or Ember and Ember (1992).

The Cross-Cultural Frequency of War

How prevalent are feuding and war cross-culturally? Ericksen and Horton (1992) report that just over half of the societies in a large cross-cultural sample engaged in feuding. They also found that feuding varied across societies from being perceived as a moral imperative to being viewed only as the recourse of last resort. In a smaller sample, Otterbein and Otterbein (1965) also found approximately half of the societies to engage in feuding.

Turning to warfare, Otterbein differentiates between *internal war*, between political communities of the same culture, and *external war*, between political communities of different cultures, and he reports that the vast majority of his sample engaged in either internal or external warfare. Eight percent of his sample of 50 societies did not engage in any type of war. For a sample of nonpacified societies, Ember and Ember (1992) found warfare to be absent or rare in 9% of the sample.

Focusing on North America, Driver (1969: 310) concludes that feuding sometimes existed, but "most of the peoples of the Arctic, Great Basin, Northeast Mexico, and probably Baja California lacked true warfare before European contact." Additionally, Driver (1969: 312) reports that whereas some societies did make war in the immense areas including the North American Sub-Arctic, the Northwest Coast, the Plateau Region of the Northwest, California, and the Southwest, "at the same time, all these areas included some peoples with little in the way of violence, raids, or feuds, and no hostilities pretentious enough to be labeled war." Jorgensen et al. (1980: 241) concluded on the basis of surveying 172 societies of western North America:

> One of the most obvious and interesting aspects of the cultures of western North America's Indians at the time of contact with Europeans was that so few societies actually engaged in persistent offensive warfare, or even raiding, yet the prospects of armed altercations deeply influenced the internal organizations and external relations of these aboriginal societies.

Based on the examination of 590 societies from around the world, Wright found that 64% of the sample either lacked warfare or engaged in only feuding and mild forms of warfare. Wright's findings thus show the cross-cultural spectrum of human societies to be less warlike than commonly assumed.

Fry (2006) lists over 70 cultures from around the world that do not practice any type of warfare. For example, from Malaysia, "there is no evidence of Semang warring with one another or with non-Semang" (LeBar et al., 1964: 185). The Saulteaux of North America, "have never engaged in war with the whites or with other Indian tribes" (Hallowell, 1974: 278). On the Hanunóo of Southeast Asia: "There are no classes, no servants, no officials, and no warfare" (Conklin, 1954: 49). For the Machiguenga of South America, "there is no warfare in their region" (Johnson, 1983: 61, 63). And Gardner (2004: 58) states "I can report a complete absence of feuding within Paliyan society and a corresponding total lack of warfare." Some clusters of neighboring societies do not make war with each other and sometimes not with any outsiders either. These groups of nonwarring societies exist in various quarters of the globe, from Canada to Malaysia, and have been labeled *peace systems* (Fry, 2006). Clearly war is not a human universal.

How Old Is War?

There are two schools of thought regarding the antiquity of war. One view holds that war is ancient, going back hundreds of thousands if not several million years (Bowles, 2009; Bowles and Gintis, 2011; Pinker, 2011; Wrangham and Peterson, 1996). The other perspective is that war is recent, originating within the last 10 000 years or so (Fry and Söderberg, 2013; Haas, 1996, 1999; Haas and Piscitelli, 2013; Kelly, 2000; Roper, 1969).

The worldwide archaeological evidence favors the latter perspective. With the exception of one possible case, the earliest evidence of warfare worldwide is within the last 10 000 years (see the range of dates in Pinker, 2011, Figure 2.2, for example). Furthermore various archaeological sequences show multiple regional origins of war from conditions of warlessness, all within the last 10 000 years (Dye, 2009, 2013; Ferguson, 2013b; Flannery and Marcus, 2003; Haas, 1999; Kelly, 2000; Maschner, 1997; Roper, 1975). Although warfare sometimes occurred among pre-state civilizations within the last 10 000 years, war became more common and intensified with the rise of the state between 4000 and 6000 years ago.

Warfare leaves its marks on the archaeological record (Ferguson, 1997, 2013b; Haas and Piscitelli, 2013). Daggers, clubs, and other specialized weapons not used for hunting; fortifications surrounding settlements; numerous interments with projectile points embedded in the bones or resting within ribcages; depictions of war in rock art; evidence that immediately following the burning of a site a new cultural style replaced the previous style of artifacts; and repetition of the forgoing diverse bodies of evidence across the archaeological sites of an area: All these types of evidence demonstrate that war was present. When multiple lines of data point in the same

direction, we can be highly certain that warfare was occurring. On the other hand, the fact that war leaves unambiguous indicators means that when we have a detailed archaeological record for an area that contains no evidence of warfare, then this shows that war was absent.

Roper (1969: 448) reviews the skeletal finds for early humans – or hominids – over the last 3 million years, and she reaches the conclusion that sporadic homicides occurred but there is no evidence of warfare in the deep past. In the absence of any corroborating evidence of warfare such as defensive sites or specialized weapons, a single victim of lethal aggression does not justify the assumption of warfare (Ferguson, 2013a). A single death could represent a murder, a group sanctioned execution, or even a hunting accident (Fry, 2006), not war. Pinker (2011, Figure 2.2), following Keeley (1996), counts several single deaths as indicative of warfare. This practice contributes to an inflated impression of war in antiquity.

Turning to the evidence, the prehistoric site with the earliest indications of possible war anywhere in the world is Jebel Sahaba in Nubia. In the Jebel Sahaba cemetery, dated between 12 000 and 14 000 years BP, 24 out of 59 skeletons display evidence of violence. Clearly this is a very high frequency of violence. Some writers attribute these violent deaths to warfare, whereas other researchers caution that homicides, executions, and sacrifices cannot be ruled out, especially in the absence of any other archaeological indicators of warfare. Furthermore, the methods used to date the site are based on comparative stratigraphy, a relative dating technique that is not as precise as absolute dating methods. Therefore, the Jebel Sahaba violence may not be in as old as has commonly been assumed (Ferguson, 2013b).

Dating from 9500 to 9000 years ago, the walls of Jericho have been taken to be the first unambiguous evidence of warfare anywhere in the world, and this may be true. However, Bar-Yosef (1986: 161) has reviewed climactic and geological evidence of flooding at Jericho and has proposed that "a plausible alternative interpretation for the Neolithic walls of Jericho is that they were built in stages as a defense system against floods and mudflows." Jericho's famous walls may or may not reflect warfare.

Haas (1996: 1360) summarizes the overall findings on the origins of war:

> Archaeologically, there is negligible evidence for any kind of warfare anywhere in the world before about 10 000 years ago …. It was only about 10 000 years ago that the niches of the world were filled in through gradual population growth, and people had to develop new settlement and subsistence strategies to extract adequate resources from decreased territory …. The archaeological record indicates that endemic warfare was much more the exception than the rule until the first appearance of state level societies between 4000 and 2000 BC in the centers of the world "civilization."

In sum, the view that war has occurred over hundreds of thousands if not millions of years into the past has no archaeological basis to support it. The oldest site worldwide, Jebel Sahaba, that might or might not reflect warfare, also might not be as old as has been assumed. But aside from the complete lack of evidence of warfare in the deep past, there are other problems with the contention that warfare is ancient. Archaeology reveals that warfare correlates with the development of social complexity in the shallow past.

Social Complexity and the Origins of War

In bands and tribes, leadership and political power are weak and dispersed, or *uncentralized*. By contrast, in chiefdoms and especially in state civilizations, political power is *centralized* at the top of a social hierarchy (Fry, 2006). In other words, social relations in bands and tribes are relatively egalitarian compared to those within chiefdoms and states that are structured according to ranks or social classes. Relatedly, foraging societies are of two general types: nomadic foragers have the band type of social organization and are egalitarian whereas complex foragers tend to be sedentary small-scale chiefdoms with social hierarchies.

Is there any relationship between social complexity and warfare? A number of studies suggest that the answer is yes. Van der Dennen (1995: 142) expresses that "one of the most consistent and robust findings is the correlation between 'primitivity' and absence of war or low-level warfare, or in other words, the correlation between war and civilization."

The nomadic band was the ancestral form of human social organizations for many thousands of years prior to the beginning of the agricultural revolution about 10 000 years ago. From diverse parts of the globe, archaeological sequences tell parallel stories about the associated development of social complexity and war. Complex foragers are societies that partially or totally gave up the nomadic lifestyle, a process beginning as early as 12 500 years ago. Comparative ethnography shows that warfare is *rare* among egalitarian nomadic foragers where most lethal disputes are interpersonal but *pervasive* among complex hierarchical foragers (Fry, 2006; Fry and Söderberg, 2013; Kelly, 1995).

The shift away from a nomadic forager lifestyle to a settled one entailed many changes. The tell tale archaeological signs of social complexity include higher population density than among nomadic foragers, larger settlements, the presence of ceremonial areas and permanent dwellings, the development of artistic styles, and variation in burials regarding amounts and kinds of grave goods deposited, burial location, and entombment preparation. Variability in burial features indicates that a social hierarchy existed wherein individuals of high social status were interred more elaborately than commoners.

Numerous archaeological examples exist that show the birth of war in association with other social changes. For instance, Maschner (1997) chronicles social changes and the appearance of war for one part of the Northwest Coast of North America. Beginning at about 5500 years ago and persisting over at least a couple millennia, skeletal trauma almost exclusively involved nonlethal injuries – and not many of these. The rarity and nonlethality of the injuries in conjunction with absolutely no other indicators of warfare strongly imply interpersonal aggression rather than war. Later in this prehistoric sequence, evidence of war appears in correspondence with certain social changes. Maschner (1997: 270) explains: "The first large villages appear, status differences become apparent, a heavy

emphasis on marine subsistence develops, and warfare becomes visible in the archaeological record."

Another archaeological sequence recounts a similar tale. In the Near East, between 12 000 and 10 000 years ago, foraging gave way to plant and animal domestication. There is absolutely no evidence of war in the archaeological record 12 000 years BP, sparse evidence for war by about 9500 years ago, and then clear evidence of spreading and intensifying warfare after that. Multiple kinds of data validate the regional origin of war emerging from a state of prior warlessness: The nature of living sites, human skeletal remains, and cultural sequence data show the development of warfare in this region.

Yet another example of the regional evolution of warfare comes from southern Mexico. Flannery and Marcus (2003) find no evidence of group conflict among the nomadic band societies that foraged in the Valley of Oaxaca for six millennia between 10 000 and 4000 years ago. Toward the end of this period, the transition from nomadic foraging to sedentary village life was underway. By 2800, three rival chiefly centers had developed, buffered from each other by unoccupied zones. One chiefdom, San José Mogote, was attacked and sacked. The survivors withdrew to a mountaintop called Monte Albán and constructed defensive walls that encircled the settlement. Eventually, Monte Albán emerged as the capital of the prehistoric Zapotec state. By about 2300 years ago, the Zapotecs had become an empire and conquered the neighboring peoples up to 150 km from Monte Albán. The evidence is crystal clear in showing, first, no war during a long nomadic forager period, which was followed by the developmental of settled, hierarchical societies and the appearance of war, which in turn was followed by the development of intensified state level warfare.

Dye (2009, 2013) considers the archaeological evidence for war and peace in eastern North America. Again we see the now familiar pattern as Dye (2009: 17) writes, "I propose that for nearly half the time that Native Americans lived in eastern North America – approximately 6000 years – peaceful relations characterized these family-level hunter-gatherers, and that violent conflict among social groups emerged only with increasingly complex forms of social and political organization."

These archaeological sequences illustrate how war has originated in particular areas and then developed along with sociopolitical complexity. These foregoing sequences demonstrate a repeating pattern. First, evidence for prehistoric warfare among nomadic forager societies is lacking. Next, as some forager societies underwent social changes toward greater social complexity, sometimes but not always war appeared in an archaeological sequence. In places where civilizations arose, the archaeological record often shows increases in the occurrence and severity of war. The archaeological evidence also suggests that warfare may be augmented by population pressures and environmental change.

In conclusion, the view that war arose recently, within the last 10 000 years, is consistent with the worldwide archaeological evidence. As Kelly (2000: 1, 2) summarizes,

> The archaeological record provides very little clear-cut evidence of warfare within hunting and gathering populations prior to the development of agriculture …. By 5000 to 4300 BC [7000 to 6300 BP], fortifications, garrisons, and site destruction at a number of locations in the Near East provide archaeological evidence for a more general prevalence of warfare …. In the relatively brief span of 4500 years, a global condition of warlessness that had persisted for several million years thus gives way to chronic warfare that arises initially in the Near East and subsequently in other regions where a similar sequence of transformative events is reduplicated.

The Reasons for War

From an anthropological perspective, the reasons for warfare or its absence are diverse. Several generalizations can frame the discussion. First, there is no unicausal explanation for warfare. Second, warfare is least developed in and sometimes absent from uncentralized societies (foraging bands and tribal peoples) in comparison to more complex and hierarchical forms of social organization (chiefdoms, kingdoms, ancient civilizations, and modern nation-states). Third, in hierarchical societies, some wars can be traced to the self-interested actions of the leaders.

Unicausal theories of warfare can be rejected as too simplistic. Some societies engage in defensive war, as was the case for the Tohono O'odham of the Southwestern United States when they defended themselves against raiding Apaches or, similarly, as was the case for 10 Upper Xingu River basin tribes of Brazil – which constitute a nonwarring peace system among themselves – as they united for defensive purposes to keep hostile neighbors at bay. Sometimes the individual status and gain of the warriors is at stake, as in the raiding for horses and scalps in the Great Plains of North America. In order to marry, for instance, a young Blackfoot brave needed horses to give to a potential father-in-law when proposing marriage. Wars are fought also for access to resources of various sorts, whether they be garden land in New Guinea, cattle in East Africa, hunting grounds in northeastern North America (following the introduction of the fur trade by Europeans), access to trade goods in Amazonia, or control of a trade route as in Near Eastern prehistory (Ferguson, 2011; Fry, 2006; Roper, 1975). Furthermore, interpersonal factors such as longstanding rivalries among chiefs or revenge-seeking for past losses come into play as reasons and rationalizations for war, factors which often are also bound up with more material or political aims. In short, the reasons for warfare apparent in ethnographic descriptions are diverse and numerous and vary from case to case.

The reasons for war also relate to social organization. There are numerous factors that dictate against warfare among nomadic forager band societies. These groups lack material goods to plunder, the populations necessary to mount much of a fighting force, the absence of anyone with enough authority to order men into battle, areas too large to defend by small bands and, in fact, little reason to do so as animals move from place to place and wild plants, tubers, or nuts are widely dispersed.

Nomadic foragers may commit homicide for personal reasons such as over a woman, an insult, or to avenge the death of a loved-one, but they tend not to go to war, group versus group, and if they do, the type of war tends to be of low intensity (Fry, 2006; Fry and Söderberg, 2013; Reyna, 1994). Meggitt (1965: 245) captures the essence of the

nomadic band circumstances that dictate against warfare as he explains that the Walbiri of Australia did not in any way emphasize militarism: "There were no military leaders, elected or hereditary, to plan tactics and ensure that others adopted the plans …. There was in any case little reason for all-out warfare between communities. Slavery was unknown; portable goods were few; and the territory seized in a battle was virtually an embarrassment to the victors, whose spiritual ties were with other localities."

Kelly (2000) has pointed out that once a society develops social segments, for example separate lineages, then feuding is facilitated. Much of what has been called tribal warfare might more accurately be called tribal feuding (see Boehm, 1987; van der Dennen, 1995; Fry, 2006; Reyna, 1994). Because there are corporate groups – social segments – and weak overarching figures of authority, an initial killing may lead the victim's kin group to seek retribution against any member of the opposing group, which then can result in ongoing cycles of violent retribution, back-and-forth. In the process, trophies may be taken, or women captured as wives. This type of fighting has been called social war by Wright (1942).

In fact, Wright (1942) developed a four-category warfare classificatory scheme and applied it to 590 societies from around the world. He used the terms *defensive war, social war, political war, and economic war*. Thirty societies (5% of the total) were found to have *no war* – that is, the literature revealed no evidence of warfare, no military organization, and no special weapons – but societies in this group were nonetheless labeled by Wright as practicing defensive war rather than nonwarring. Wright assumed that members of such societies would fight to defend themselves if attacked, but in fact ethnographic accounts show that this is not always the case; members of such societies typically flee from would-be or actual aggressors (Fry, 2006).

Another 346 societies (59% of the sample) were rated by Wright (1942: 546, Appendix IX) "to be unwarlike or to engage only in mild warfare," provided that "no indication was found of fighting for definite economic or political purposes in the more specialized literature." Social war consisted, for instance, of headhunting, revenge-seeking, and feuding. The inclusion of feuding as a type of warfare contributes to the social war category being the largest of the four classifications.

It is worth noting that adding together the defensive/non-warring group and the unwarlike/mild-warring social war group shows that nearly two-thirds of the total sample (64%) were nonwarring or mild-warring. The rest of these 590 societies were determined by Wright to engage in war for economic or political purposes (29 and 7% of the total, respectively). The expansion of the ancient Zapotec empire in order to dominate rivals and exact tribute from the hinterlands provides an example of political warfare (Flannery and Marcus, 2003). Often economic and political reasons for war go hand-in-hand.

On the basis of a career spent studying the anthropology of war, Ferguson (2011) emphasizes the importance of considering the self-interests of the leaders. Those who actually start wars tend to be the ones who benefit most in terms of acquiring wealth, resources, and power. "To understand war, then, one must focus on the decision makers. That directs attention to the sociopolitical structure of a society. What different kinds of people, groups, and institutions contribute in what ways to decisions, and what are their interests in a given situation?" (Ferguson, 2011: 265). Of course the leaders, notes Ferguson (2011: 265), tend not to state to their followers, "go risk your life because it is good for me," but rather emphasize the importance of courage, the necessity of defense, the satisfaction of revenge, or the spoils of war for the warriors and society. Once a society has developed a complex of warrior values and institutions such as bravery, obedience, loyalty, and fortitude, coupled with a standing army and a social chain of command where refusal to fight can be severely punished, the rationale for going to war also can be justified as moral and right.

Conclusion

Anthropology shows that numerous factors can contribute to warfare, for instance, a quest for safety and security, a scarcity of or competition for resources, a desire for revenge, and the political and economic self-interest of the decision-makers themselves. Anthropology also shows that living without war is possible as nonwarring societies and nonwarring peace systems do exist (Fry, 2006). It is clear that the frequency and intensity of warfare correlate with social complexity, as reflected in both the worldwide archaeological record and in comparative ethnography of nomadic bands, tribes, chiefdoms, kingdoms, and states. When humankind made a living as nomadic foragers, the species was not plagued by warfare. Warfare has arisen repeatedly within the last 10 000 years and spread in recent millennia along with certain changes such as population increase, settling down, the development of social hierarchies and authoritative leadership, or, in a word, with the development of more complex forms of social organization, especially the state. The key question for the twenty-first century is whether humankind will go down fighting or, alternatively, give up the practice of warfare and resolve their differences without bloodshed.

Abstract

Conflict is a regularly occurring and socially organized phenomenon. Organized conflict in its nondestructive forms is a condition for the differentiation and expression of interest as well as for endogenous social change and the processing of exogenous stimuli of transformation. The self-stabilization of social systems and social change could not be analyzed without giving central attention to conflicts and their organization. Conflicts can be classified in respect of their stronger or weaker social embedding and in respect of the higher or lower incidence of violence in a field with four extreme types: the strongly embedded forms of warring and procedure and the weakly embedded ones of destruction and avoidance.

Conflict is an action based upon the perception of partially incompatible interests or intentions between two or more persons. This perception need not be shared by both sides. What should be considered as an interest or intention requires interpretation in respect of the context. For analytical purposes, these concepts often remain projections; they should, however, be grounded in observations of statements or of chains of action that are open to operationalization and falsification. They are necessarily culture bound and may even be a matter of debate within a given culture. Furthermore, the perception of conflict does not need real intentions or real persons in order to generate action. The assumption of witchcraft, e.g., may generate virtual feuds.

Goals of an Anthropological Theory of Conflict

An anthropological theory of conflict can

1. Contribute to the explanation of violence. Conflict is, however, not the only element that will contribute to an explanation of violence. Violence may, for example, be needed as a strong symbolic marker for ritual purposes. And it has to be underlined against a popular perception of 'conflict' that not every conflict is violent.
2. It can contribute to a theory of the attraction or displacement of emotions. The hatred against foes, for example, is not something natural but is an outcome of specific constructions of conflict.
3. The theory of conflict competes with culturalist approaches as an explanation of social cohesion. Forms of conflict regulation can reduce the relative conflict intensity between persons and, thus, create their allegiance to the system or organization that provides for this conflict regulation.
4. It contributes essentially to a theory of social evolution. The ways by which a society regulates conflict operate also as means for the selection of alternatives for its future.

The History of Anthropological Research on Conflict

Anthropological research on conflict is a history of many hopes lost and few results kept. It was a classic conviction (going back to Thomas Hobbes) that a 'primitive' or 'natural' state of society would be characterized by omnipresent violence. Konrad Lorenz (1966) proposed a biological paradigm insisting on a genetic program for violence, which Ashley Montagu (1968) convincingly opposed. One finds a broad variance of behavior toward potentially conflictuous situations in all different forms of human social organization. If something is encoded, it is both a potential for aggression on the one hand, and a potential for flight and conflict avoidance on the other.

Sahlins' (1961) study of the Nigerian Tiv, of 'lineages of predatory expansion,' suggested to some that genealogical closeness generally made violent conflict less probable. Barth's (1959) study on Swat Pathans has shown, however, that this pattern cannot be generalized, not even to lineage societies. Confrontation may follow from alliances against one's closest competitors, even if they are close relatives.

Types of violent conflict had been associated with different 'cultural levels' even by Malinowski (1941). It was argued that on the first levels there would be less violence. Other authors (e.g., Chagnon, 1968) assumed for these societies a specific type of resource competition as a strong motive for conflict (cf against these Hallpike, 1973). Helbling (1999), however, has shown that the occurrence and intensity of conflict is not directly correlated with different types of social organizations, but rather to population density within a given type of social organization. Thus swidden agriculturalists or hunter-gatherers with a high population density may also show a high incidence of conflicts.

Marcel Mauss (1923/24) built his theory of exchange ('the gift') in order to provide a theory of peace. Relations of reciprocity that serve as a basis for exchange including market exchange are, however, compatible with relations of warring. Polanyi (1968) showed this for the seasonal warfare of the kingdom of Dahomey in West Africa.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12232-9

For a long time, one of the most prominent anthropological theories of conflict was Max Gluckman's (1956) theory of cross-cutting ties, which would hinder the outbreak of conflict because the potential foes were always also indirectly linked by alliances. Hallpike (1977), cf Schlee (2000) has shown, however, that cross-cutting ties may as well work the other way round, as an organization of competition, thus fostering conflict.

A stable achievement of anthropology is Sumner's (1911) ethnocentrism theory. The organization of violence requires the definition of boundaries. Leach (1965) added dryly that killing is the most powerful tool of classification – for the survivors.

Another result, not so readily identified with a single name, is the perception that factors of social organization have a higher impact upon successful strategies of violent conflict than pure technology. Although early historical work insisted strongly upon the effect of the arrow, the warrior mounted on horseback and firing arms, or even more so bomber aircraft, later research, however, stressed rather the organization of access to technology, the transmission of knowledge and training of skills and, last but not least, the social organization of risk perception. Violent conflict requires that risks are played down against potential benefits.

Methodological Problems of Conflict Research

That a human action is categorized as conflictive requires that it fulfills in its form some preestablished patterns. That pattern perception also means that contingent action without conflictive intention is likely to be interpreted as conflictive if it is harmful and if a meaning may be interpreted into it.

Societies tend to present conflict as unforeseeable or even chaotic. Sometimes conflict is even excluded from a society's self-representation. Conflict may be characterized as evil, or as a psychological and not as a social phenomenon. The less conflict is 'normalized' in institutional forms of low intensity, the more difficulties will fieldworkers face when trying to learn something about existing conflicts or the pattern of their organization and resolution. The existence of conflicts may just be denied, or existent conflicts within a group may be hidden behind other conflicts with outsiders.

Conflict as Embedded Social Action

Anthropology has challenged the popular perspective of conflict as chaotic and disorderly. The image of chaos is, however, based upon experience, Successful conflict management in the interests of the actors requires surprise, which may create the impression of unforeseeability. Conflicts follow, however, socially ordered paths. Rather like in the case of avalanches, the exact moment and the intensity are difficult to foresee, but one knows in a given environment where they may happen and which path they will follow. Anthropological research has shown that even violent conflict follows culturally encoded patterns, has institutionalized forms, and is controlled and directed in its appearance. This has been called social embedding (Elwert et al., 1999).

Embedding is the ensemble of moral values, proper norms, and institutional arrangements that set limits to a specific type of action and make simultaneously the outcome of these actions calculable. The fact that conflict has both controlled and foreseeable aspects and an element of surprise creates a hybrid structure. Therefore, one may speak of partial embedding.

Conflict situations are characterized by a relatively high autonomy of time use for one of the actors. The outcome in conflicts is unforeseeable in respect of the relative gains and losses. Society, on the other hand, creates foreseeability through routines and norms that channel the realization of conflict. Norms as a means of channeling conflict not only have a stronger effect than just routines, but are also much less flexible than routines. It is, therefore, inherent to the character of social norms that they will be 'underlived.' One should therefore not expect norms regulating social conflict to be followed 100%.

The concept of norms allows us to differentiate two types of conflict: normative conflict versus actor conflict. In the former, a person or a group of persons clashes with a norm when violating other persons' or groups' rights. In the latter, individuals or groups clash and try to harm each other in a field of action that has normatively defined boundaries but where neither side can claim norms protecting its goals.

Forms of Actor Conflict

The multitude of concepts used in order to describe conflicts (war, genocide, competition, feud, legal battle, etc.) can be ordered in a field with four poles (see **Figure 1**). To speak of poles means that the empirical cases and emic categories may be positioned between these abstract ordering categories. The criteria are more or less violence, and stronger or weaker embedding. The category 'warring' includes both feud and war. A war is a violent conflict that includes physical risks but is limited by some rules. A feud is a violent conflict with stronger embedding and in general also less violence than wars. It is defined as a violent conflict where the potential victims, the place of conflict, the time of conflict, or the weapons allowed may be the matter of a binding agreement. A necessary condition for the definition of feud is that the means to end the conflict is part of the agreement. Feuds and competitions cannot be clearly separated, as all these categories have a fluid transition. Competitions, however, should rather be seen as being part of procedures. Procedurally organized competition, measured in abstract parameters (e.g., money or speed), may allow for an almost continuous conflict without violence.

In legal studies, procedures are defined by a specific – ritual – form, whereas anthropology as a comparative science cannot only rely upon conceptualizations defined by the actors. An

	More violence	Less violence
Stronger embedding	1	Procedure
Weaker embedding	Destruction	Avoidance

Figure 1 Differentiations of conflict.

anthropological concept of procedure, therefore, has to take up suggestions formulated by Niklas Luhmann (1969). A procedure is distinct from daily interaction by its form and ordered sequence of action. Elections, court cases, and auctions have also been seen as conflict resolution procedures. During a procedure, some power differentials are suspended. It may, for example, be excluded that a stronger person physically harms a weaker person during the procedure. A procedure has an outcome with consequences in action. Who will profit from the outcome is, in principle, open. It should be called procedure only when it ends in a conclusion that has meaningful consequences for action.

The conclusive procedure has to be distinguished from the pending procedure: something that has the ritual form of the procedure but that never comes to conclusions that are consequential. Thus, the pending procedure is not a way of conflict resolution but a way of conflict perpetuation. Pending procedures can have a high annoyance potential and are rather forms of warring with reduced violence.

Destruction (e.g., genocide) is distinguished from warring as the goal is the total annihilation of the other. There is no agreement that binds both partners together. Nevertheless, the ways the other side is destroyed follow a culturally encoded pattern. There is no human society that allows killing that does not simultaneously have some rules for 'proper' killing.

Avoidance is a concept rarely included in theories of conflict (Radcliffe-Brown, 1952), but to have a complete conceptual structure we need to consider also this 'zero-case.' In some societies, avoidance is the dominant mode of dealing with conflict (see Elwert, 2001 on the Byalebe of West Africa). In a situation where avoidance is dominant, it is more probable that people switch to destruction than that they switch to procedure.

The Normative Conflict

A normative conflict is a conflict in which a person's behavior toward another person or a thing, which is meaningful to a person, conflicts with a norm. In this context, norm is meant in the strict sense; it requires both monitoring and sanction. Prescriptive or prohibitive formulas without a sanction probability should be considered moral values, not norms. This definition is different from those given within societies. There are, in general, more prescriptive or prohibitive formulas that are considered 'norms' than those whose infraction is really prosecuted.

The monitoring is necessary in order to create a sanction potential. Monitoring is a sensitive element of this process. In some societies, monitoring is restricted to specialists or to persons with a recognized claim to competence (police, priests, and soothsayers).

Reactions to norm infraction range over a wide spectrum. In state societies, the dominant mode of reaction is typically the sanction by a central specialized apparatus, the coercion instance. Another solution is the 'sanction-service.' In state societies, this may appear parallel to the centralized apparatus; it is then often considered to be illegitimate, for example, as a Mafia (Krauthausen, 1997). In stateless societies, there may be specialists for sanction services, organized as corporations, age grades, or secret societies. A third option is self-help, which may take a form similar to feuding (Spittler, 1980). Self-help requires some kind of broader agreement that a norm has been transgressed. This can be a court decision, which then legitimates the persons considered as victims of the norm infraction to take action or to hire specialists for this purpose (cf Würth, 2001 on shari'a courts in Yemen). A fourth option, which again is a zero-option, is ignoring the conflict. If there are no strong central instances or sanction services available and if the dividing line between the actor conflict and normative conflict is blurred, this is a common solution.

Sanctions are not only physical sanctions (as corporeal harm or mutilation, restriction of movement, or material and economic fines) but also loss of status or attribution of negative reputation. The reputation sanction is very common in those contexts where a person can hardly escape contact with those who share the negative evaluation of the culprit. Since societies are never homogeneous, subgroups may not share specific norms (Pospisil, 1958). The reputation sanction is then limited in its efficiency. The redundancy of overlapping reference groups, each with a sanction capacity, can cope with that (Elwert, 1980).

The normative conflict is a two-tier process. The first element is the infraction; the second is the sanction process. That the infraction is an infraction is, however, only definitely clear after the sanction process. The working of the sanction process may be expeditive (e.g., lynching) or procedural. The expeditive reaction is based upon a single decision or a turning point from when on a plurality of single decisions is valid enough for action. All human societies – not only the 'modern' ones – know, however, the advantages of procedural forms of sanctioning over the expeditive ones. Truth may be a matter of disagreement, and the loss or investment of time characteristic of procedures may allow information to be validated and emotions to cool down. Procedures may, however, also be used for the alternative purpose of steering the multiplicity of perceptions into just one established truth, and to stir up the emotions in such a way that sanctions become more probable or more violent.

The Attraction and Displacement of Emotions

To live with emotions and act upon them requires some societal agreement. The popular notion that conflict is motivated by emotions does not hold against anthropological evidence – at least insofar as recurring conflicts are studied. People hardly react to emotions, but to assumed or perceived goals of action. The reaction in a conflict situation has higher strategic qualities if it is not based upon emotion but upon cool calculation. To 'show' emotions may, however, be very important in order to legitimate one's action in a conflict situation, or in order to impress the adversary.

Actions in conflicts, however, can attract emotions. This is correlated with changes in the structure of relevance; it may help to concentrate resources to the conflict. Actor conflicts are strong attractors of emotion, even more so if violence is implied. In any procedural treatment of conflict, and especially in normative conflicts, emotions can be less intense. They may

appear comparatively detached or displaced. A society that gives preference to normative conflicts and that privileges the procedural treatment allows for the displacement of emotions. The literary representation of conflict or sport competitions – a form of conflict with lesser implications to one's personal life goals – may then attract stronger emotions than those linked to lived conflict.

Conflict Motives

Motives to enter conflicts can be grouped into three broad categories: honor, power, and material gain. Each of these three general motives has its own definition of who won in a conflict situation. What, for example, an outside observer may see as an economic loss, may appear to the insiders as winning prestige. In most cases, however, there are several motives overlapping, and this can make it difficult to define who won in a given situation. To distinguish between these three categories of motives is, however, helpful in order to perceive different consequences of their priority for the respective organization of a conflict. If honor is the major goal – and even more, if honor may be even gained by a dead person declared to be a hero – then the propensity to risk increases. This may create patterns of recurrent warring, since new generations need new prestige (cf Evans-Pritchard, 1957 on Azande warfare). In the case that power, the control over persons, is the goal, the end of the conflict has to be such that the winning side retains a coercion potential over the losing side. If material gain is the goal, then it may be reinvested, in a self-perpetuating process, to gain even more.

Systems of blood feud or vengeance are often dominated by a system of attribution of honor and shame. To kill a person may create honor. If this killing is not retaliated, this creates shame. Vengeance 'washes away the shame' and reestablishes honor (Schwandner, 1999).

Behind a smokescreen of ideological motives, warlords exhibit a very clear priority for motives of economic gain, whether the means are peaceful or violent. This entrepreneurial activity creates a market without the typical embedding for peaceful markets, a market of violence (Elwert, 1999). Whether warlords subjectively give priority to noneconomic goals or not, they need weapons and soldiers (even if they call them volunteers) in order to reproduce their activity. The gains from robbery, blackmail, hostage taking, customs, and trade (especially in valuable items such as precious metals or stones, drugs, and weapons) have to cover expenses for the violence and generate a profit.

Group conflicts may originate in divergences of interest between the groups or they may be produced by the construction of such contradictions. In the latter case, the purpose is a strategy that aims primarily upon the control of power within that group, an endostrategic mobilization. In such a process, the outside conflict is heated up in order to homogenize the group, to push forward new norms or structures of leadership. Boundaries to 'the others' are created or become accentuated. Endostrategic mobilization is typically the instrument of would-be elites who want to gain power and therefore portray the actual elite as persons who do not sufficiently defend collective interests, or as agents of outside forces.

Conflict Regulation and Cohesion

It seems at first sight paradoxical to associate the social organization of conflict positively with social cohesion. Since anthropologists no longer believe that there is a natural harmony among human beings, however, one cannot escape the notion that the normalization and institutionalization of conflict in specific forms is an essential condition of social cohesion. Divergence of interest is omnipresent among human beings. If there is no channeled way to express it, then random conflict and – even more so – avoidance reduce chances for cooperation. Cooperation requires not that conflict is repressed but that it finds predictive ways of expression. Less destructive forms of conflict and especially forms that maintain both sides' interests in form of compromise ease the readiness to enter conflicts. They do so because the lower risk threatens less the conditions of cooperation during or after the conflict. Thus, an institutionalization of conflict may increase conflict incidence if conflict becomes less violent within the respective entity.

A social group with a common reference is not necessarily a 'conflict group,' a group capable of acting collectively against one other. A conflict group requires an internal sanction capacity. Without it, collective action would be undermined by free riders who want to enjoy the benefits of a victory but avoid the risk of the conflict itself. The creation of such a conflict capacity through an internal sanction system is an important indicator of a mobilization potential for civil strife and civil war.

We can observe that we-groups, organizations, or societies tend to reduce the violence of conflict within their respective boundaries. But this tendency does not create a general pattern. As cooperation creates resources, material or immaterial (such as honor), these resources may motivate further conflict. Thus, the violence of conflict within groups may be stronger than the violence between them. As long as these conflicts do not turn into a systematic destruction of a given subgroup, the entity's cohesion may be maintained nevertheless.

The economist Albert Hirschman (1994) has observed something about modern societies, which probably can be generalized to other societies as well: Group cohesion is strongly correlated with the access to accepted modes of conflict regulation. Shared cultural values, even if they are as emotionally binding as language or religion, do less to explain social cohesion than the presence of institutions that appear to give a fair chance to realize one's interests with reduced destructive risk. From an anthropological point of view, one has to add that procedures create a higher cohesion than other channeled ways of living a conflict.

Hirschman has further shown that those procedures which favor more-or-less solutions (incremental conflict resolution in the authors' terminology) have a better chance to create cohesion than those with either–or structure (alternative conflict resolution). The compromise maintains elements of interest of both sides. This eases the identification with the outcome of the conflict regulation. This perspective has been applied in an anthropological perspective to modern nations. It could be shown in one case that irrespective of cultural parameters such as language or religion, it is the deprivation of access to normatively regulated institutions of conflict resolution that

furthers processes of fission and separatism (Elwert, 1997). For African states, it has been shown that the classical ignition spark for civil war is the arbitrary use of violence by state agents (Wirz, 1982).

Institutions of Conflict Regulation as Central Determinants for Processes of Social Transformation

Ralf Dahrendorf (1954) has argued that the forms of conflict regulation are central for the difference between paths of social transformation. The normative structure most often (but neither always nor exclusively) ensures a society's reproduction and its sameness over time ('identity'). Social change requires breaks in the reproduction of sameness. It can, however, not proceed by 'anything goes,' since the end of reproduction would undermine further change. Stimuli for change, whether they are endogenous or exogenous, have to be treated as alternatives to something, and not as unrelated events. Alternatives are never abstract, they imply persons' intentions. This gives the organization of social conflict the key role in social change to conceive and select alternatives.

Societies that give preference to the normative conflict increase the foreseeability of one's own actions. As long as one follows the norms, the risk of conflict is reduced. But this produces overall a higher conflict-processing capacity. There is less relatively randomized conflict and thus more possibility to engage into ordered conflict. A higher conflict-processing capacity means more variation. If the society uses these institutions in order to select not only winners and losers, but also elements of social order, forms of consumption, and new products of human activity, then innovation can gain acceptance. It is the higher selectivity that reduces the fear of new elements of social order.

It cannot be stated, however, that such a society would be 'more highly developed' than others. Depending upon the type of social environment, different types of conflict regulation appear as optimal adaptations (Hallpike, 1973). Avoidance-biased societies are among the most expansive types of social organizations in an environment characterized by raiding, especially slave raiding. Avoidance produces a high dispersion and thus hinders the population concentrations necessary to make slave raiding a profitable enterprise, e.g., in some regions of the Sahel and the Sudan. At the margins of aggressive imperialisms, feud-biased societies appear to be one of the most stable arrangements. These societies keep internally a high level of warring competence that acts as deterrent or repellent to these imperialist forces – as can be shown in the case of the Caucasus or some regions of the Balkans. If societies interpenetrate each other by means of a reciprocal competition on their markets, a high innovation capacity gives an edge to this competition. Procedure-biased societies appear to be especially strong in this respect, e.g., some medieval oriental societies and some modern Western ones.

Retaliation, Compensation, and Punishment

In Sections The Normative Conflict; The Attraction and Displacement of Emotions; Conflict Motives; Institutions of Conflict Regulation as Central Determinants for Processes of Social Transformation, although they were not typological but addressed general issues of conflict theory, a number of types of conflict and of conflict management have been described (normative conflicts, especially in state societies; actor conflicts; blood feud and vengeance, warlordism; feud-based societies, procedure-biased societies). What remains to be done is to put these types in a comparative framework. Beyond the comparison of pure types, one has to consider how they coexist and interpenetrate in the real world.

Both violent action, like declaring and waging a war, and legal procedures or peaceful consultations can follow the logics of retaliation or of punishment. Retaliation tends to be associated with compensation (because paying compensation for some damage one has done is the means to avert retaliation) and both are based on the idea of equality of the partners on the discursive level, whatever the real power differential may be (parties tend to have different negotiating powers and ways to make noncompliance unattractive for their counterparts). The idea of punishment differs from that. Punishment takes place in the name of a higher entity, be it God, the State, the Law. Those who inflict it might even pretend to regret it and depict themselves as merely having to obey some normative order, said to stem from 'above.' (These spatial metaphors, horizontal versus vertical relationships, higher and lower classes, and tops and bottoms of hierarchies, are inevitable not only in popular parlance but apparently also in social theory.) When talking about the logic of horizontal versus vertical forms of conflict management, the authors refer to ideal types that reality always mixes.

One example of such a mixture or interpenetration can be drawn from conflict management in a region characterized by weak state control (like an inaccessible region in the African savannah) or in a subculture or social environment from which the state has withdrawn its day-to-day interference (like the scene of gangs and gang warfare or illegal but uncontrollable sectors of the economy). Here, one finds regulation by non-state actors to predominate. Also, here deals are struck, conflicts are resolved or at least managed, revenge may be taken or averted by some act of mollification, and so on. In all this, such settings resemble stateless societies in precolonial Africa, or other such social configurations that have come to be known as acephalous ('headless') in the anthropological literature. But in these settings, the state is not completely absent. It does exist in the background of all conflict management processes taking place outside government institutions. One of the parties can always threaten to call the police or to take legal action if the deal achieved in the sphere of custom, informal arrangement, mediation, or arbitration by non-state actors is not satisfactory (and if other conditions, like the courage to oppose these actors, are given). So all these nonstate forms of regulation take place in the shadow of the state and those who strike a bargain there might have to take the state, although it remains passive most of the time, into consideration.

Another example of the interpenetration of these different modes of conflict management can be found at the

global level. The world is an acephalous society. There is no world government and the states that make up the global diplomatic system are formally equal. In such a setting, one would expect retaliation and compensation as the primary modes of conflict management, and indeed much of what one observes on the international scene can be reduced to that. Still, appeals to some more normative level, and claims to obey higher imperatives rather than simply to follow material interests are constantly made, no matter how thinly the latter may be disguised. Even very strong politicomilitary powers taking action against relatively weak ones would seek 'coalitions' with other powers or legitimation by some international organization without a military arm of its own to be able to depict their cause as just and their action as carrying out a punishment for a crime against a broader set of values than a specific national interest. So also here the language of 'higher' authority penetrates the world of formal equals (Schlee and Turner, 2008).

Changing Identifications and Alliances

For the sake of simplicity, so far the authors have written about actors and groups of actors as if they were well defined and about their perceived interests as if they were constant over a significant period of time. Important research questions arise from the fact that they are not. Especially, situations of intensified conflict are characterized by acceleration processes of redefinition of social identities (identification) and changing alliances (alliances are always made up of groups defined as different). So one way to acquire or shed supporters is to enter into wider or narrower alliances with 'others,' often on just one issue of shared interest or a limited set of issues. The other one is to let one's own we-group shrink or widen by adopting exclusive or inclusive forms of recruitment or by engaging in discrimination against certain sets or subsets of members.

Changes in the composition of a conflict party (be it a group or/and alliance) are likely to affect the perception of group interests, because different people have different values, preferences, and definitions of a resource, skills, strategies, habits, etc. Costs and benefits, including gains and losses in a violent conflict, are measured against such changing perceptions of groups and alliances with changing compositions.

A core issue of conflict theory therefore is the dynamics of the composition of conflict parties. Identification often takes place along certain lines that have become conventional in the modern world, like nation, ethnicity, language, or religion, but 'switching' between these is possible (Elwert, 2002). Ethnicity can be nonterritorial or it can follow the nation-state model and become territorialized (Schlee and Shongolo, 2012). To find out about the rationality of identification in conflict situations requires an exploration of the options, i.e., the forms of identification and alliance available to strategic actors and the degrees of freedom they have in choosing among them (Schlee, 2008). That identifications, goals, and strategies change in the course of a conflict, contributes to the general emphasis of a newer kind of conflict theory, which explains conflict configurations at any moment as a result of conflict dynamics rather than preexisting structural givens (Zitelmann, 2004: 51).

Conflict Mediation

Isak Svensson, Uppsala University, Uppsala, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Mediation is a form of conflict management that is based on conflicting parties' ultimate acceptance. Conflict mediation is a growing field, both academically as well as in terms of policy and practice. This article discusses the concept of conflict mediation and suggests that mediation research has developed in three major waves of research. We also examine what mediators do when they mediate, the practice of mediation. This article ends by an exploration of two major research areas in mediation research: the question of timing and mediation strategies.

Introduction

Conflict mediation is a growing field, both empirically in terms of number of active third-party mediators and mediation-supporting institutions around the world, and academically, in terms of an expanding research agenda. (There are some recent reviews of the mediation literature, which complements what is written here (Greig and Diehl, 2012; Wallensteen and Svensson, 2014).) This article will summon the main insights from mediation research. It consists of five sections: (1) a discussion on the definition of mediation, (2) an exploration of development of mediation research, (3) a discussion about the practice of mediation, and (4) an examination of mediation timing and mediation strategies.

What Is Mediation?

Mediation in the context of armed conflicts – conflict mediation – represents an important set of diplomatic measures taken in order to resolve or manage conflicts. Mediation has been defined in various ways. Bercovitch defines it as a "process of conflict management, related to but distinct from the parties' own efforts, whereby the disputing parties or their representatives seek the assistance, or accept an offer of help from an individual, group, state or organization to change, affect or influence their perceptions or behavior, without resorting to physical force, or invoking the authority of the law" (Bercovitch, 1992: 8). A later definition defines international mediation as "a reactive process of conflict management whereby parties seek the assistance from, or accept an offer of help from, an individual, group, or organization to change their behavior, settle their conflict, resolve their problem without resorting to physical force or invoking the authority of the law" (Bercovitch and Houston, 1996: 13). Notably, there is a slight difference in regard to what the mediators actually do: whereas the previous definition emphasizes the changing of perceptions of the parties, the latter one instead focuses on resolution and settlement of the issues at stake. International mediation can also be conceptualized as "the intervention of a third party; it is a voluntary process in which the parties retain control over the outcome (pure mediation), although it may include positive and negative inducements (mediation with muscle)" (Miall et al., 1999: 21–22). Furthermore, mediation can be seen as "a mode of negotiation through which a third party helps the parties find a solution that they cannot find by themselves" (Zartman and Touval, 2007: 437). In other words, mediation is "a form of conflict management in which a third party assists two or more contending parties to find a solution without resorting to force" (Kleiboer, 1996: 360). The common elements of these definitions are three. First, mediation represents efforts to manage or resolve conflicts constructively. It is a group of diplomatic techniques that can be utilized by diplomats, but also by organizations or citizens. Although its essence is peaceful (most definitions exclude the use of force), not all definitions exclude the use of pressure, including *threats* of force. There is nothing in the definitions of mediation which preclude heavy-handed pressure from the third party upon the parties in conflict. In fact, the ability to influence the conflicting parties, the degree of leverage, has been seen as one of the most important explanations for why some mediators are more successful than others (Zartman, 1995). Constructive mediation is here understood as a process in the direction toward more peaceful interactions between the parties in the conflict. The aim with mediation (although not necessarily its only motive) is to seek a solution to a conflict or a de-escalation of the conflict behavior, and thereby it represents a constructive management or resolution of the conflict. Second, mediation is voluntary in the sense that the conflicting parties contain a final veto-power over the outcome of the mediation process. Put differently, mediators might impose themselves and pressure the parties to accept a particular peace deal, but at the end of the day it is up to the parties to accept the mediated outcome. Third, it is an activity performed by third parties. A mediator cannot therefore be a representative of one of the sides (primary actor). It can be an external actor that is emerged in the conflict on one side (secondary actor). A third party is however not necessarily external to the conflict. There are internal third parties that come from inside the conflicting society but still can act as third parties. In fact, research shows that such domestic resources for peace have some particular advantages to bring to the peacemaking processes (Wehr and Lederach, 1991; Svensson and Lindgren, 2013). Hence, conflict mediation is a way of managing or resolving armed conflicts that involves third party actively seeking to bridge the gaps between the main antagonists. It differs from other attempts to regulate conflicts in the sense that it does not require the parties to beforehand accept the final outcome of the mediation process. It therefore depends on the acceptance

of the parties, and any proposal of a mediator needs to be accepted by the parties in conflict. It does include the use of direct force, although various types of political and power pressure are not unusual in some forms of international mediation.

Mediation Research

Mediation research has expanded through three major waves. The traditional approach to mediation was drawn from social psychology. Typical of this style was the work of Herbert Kelman (1997), focusing on particular relations (notably Israel–Arab relations). The main research problem has often been how mediation processes can help overcome barriers of distrust and misperception as well as to communicate shared values of peace. The social-psychological approach highlights limitations in the cognitive, emotional, or organizational capacities and has produced a wealth of insights, also applied in real life situations, notably in the form of problem-solving workshops (Rubin et al., 1994; Fisher, 1999).

A second mediation research tradition has been anchored in rational choice theory, focusing on cost-benefit calculations of the parties in a conflict. A central research question has been whether mediators can exert leverage over the parties in a way that changes such calculations. If mediators can contribute to increase the perception of costs associated with continuous armed conflict (the mutually hurting stalemate), and/or increase the attractiveness of a potential solution (mutually enticing opportunities), then they stand in the best position to influence the basic dynamic of conflicts. Mediators who carry hard-hitting sticks or carrots that can wet the appetite of the parties, are most likely to be successful as peace-brokers (Zartman and Touval, 1985; Stedman, 1991; Touval, 1992). It differs from the social-psychological tradition in a basic sense: the underlying assumption of the theoretical frameworks is not one of limitations of rational decision making of conflict actors, but rather the rational decision derived from the costs and benefits of war and peace.

A third mediation research tradition that has dominated the discourse for the past decade has been the bargaining perspective (Beardsley, 2008). In its systematization it has built on the earlier but moved into a firmer vocabulary and stringent theoretical requirements, paralleling developments in other field (Fearon, 1995; Kydd, 2010). At the same time, it has relied more heavily on data that oftentimes have been collected for particular, even different, reasons. Within this field of thinking, information failures and commitment problems have been the main concern. Information failures are postulated to occur when parties in conflict simultaneously have incomplete information about each other, and reasons to mislead the other side (for instance, by bluffing about real strength to get a better bargain, Fearon, 1995). The mediators' contribution could be to overcome this problem. If they possess information that the parties do not have, and if they can credibly transfer such information between the parties, the information failure problem is managed, and the parties will not need the battlefield to correct their information about each other (Kydd, 2003). This rests on two assumptions, (1) that the mediators can access information that is private (basically information about the antagonists' strength and willingness to fight), and (2) that mediators credibly can convey such information. Empirically, it should be noted, it remains to examine the validity of these two assumptions.

The Practice of Mediation

What do mediators do when they mediate? Put differently, what is the practice and techniques of mediation? A set of mediation activities can be identified. We can understand them if we relate the notion of 'mediation' to the notion of 'conflict.' Conflict can be defined as "a social situation in which a minimum of two actors (parties) strive to acquire at the same moment in time an available set of scarce resources" (Wallensteen, 2011: 16). Hence, a conflict consists of contested issues – aspirations over limited resources, a behavior ('strive' in the definition above, in the context of armed conflicts this implies the use of violence), and it represents a social situation where parties or actors are active. Issues, behavior, and actors are the three basic elements in the conceptualization of what we mean with conflict. Hence, conflict mediation can be seen as third-party-based processes of handling all or some of these dimensions: resolving conflicting issues, de-escalating or terminating violent conflict behavior, and transforming the actors. It is possible to discern seven categories of activities that mediators pursue when mediating, through which they are pursuing activities aiming at influencing issues, behavior, or parties in conflict. Not all mediators engage in all activities, and some mediators may specialize in a particular conflict in only doing one of these activities. As the field of mediation has started to move toward professionalization, it has also led to a higher degree of specialization. Hence some type of mediators may, for instance, work primarily with getting the parties to de-escalate their violent interaction, whereas others may work primarily on reaching an agreement on the contested issues.

The seven categories of activities for mediators:

1. crafting a mediation mandate
2. creating relationships
3. resolving the contested issues
4. handling process issues
5. dealing with regional actors
6. increasing the cost of conflicts and benefits of a solution
7. implementing the agreement

First, mediators craft a mandate for the mediation intervention. The mandate is important in mediation, as it frames the possibilities for the mediator to act in the conflict (Svensson and Wallensteen, 2010). Surprisingly, relatively little research has been conducted on mandates, in particular in relation to the central role that mandates have been playing in research and policy-making of international peacekeeping. A mandate is the basis for the intervention, on which the mediator has its rationale. Mediators can derive the mandate from the parties themselves; from an outside actor, such as a state or an organization; or they can stipulate the rationale for themselves, without connecting it to the parties. The mediator then often enters without an explicit mandate (a self-imposed mandate). If the mediator has an organizational mandate, it gives him or her the freedom to intervene regardless of any activities on the side of the organization. Mandate is often something that is created before or at the

onset of a mediation intervention. It would be too simplistic to see this in terms of a one-term event occurring only at the initiation of the mediation intervention. In fact, mediators have to interpret their mandate in light of evolving developments, and these interpretations may shift over time. Moreover, mediators can renegotiate their mandate in terms of getting more or less room for engagement and bear more or less expectations of what they will do. Furthermore, mediators can renew their mandate, which will give them opportunities to pressure the parties to make an agreement if a current mediator is ending his or her assignment. In an environment where there are several mediators, they need to show their usefulness. For mediators, it is not uncommon that they have to explain the mandate for the parties – the reasons for their involvement and the legitimate basis for their intervention. Since conflict parties are not unitary actors, but consist of a set of individuals, subgroups, and fractions, and also exist in a society where there are many different actors, this means that mediators commonly have to explain the basis for their involvement to new segments of the parties or the society.

Second, mediators strive to create relationships between the parties as well as a sense of understanding and empathy for each other. This also involves creating a trust in the mediator and the mediation process – thereby getting the parties to open up for interactions without their own primary group. Building trust is important both to overcome misperceptions between the belligerents and to move the mediation process forward. Parties in conflict usually have created negative stereotypes of the other side and a great sense of mistrust is common between the parties. This could hinder the mediation process from even starting, as the belligerents might not want to talk to each other or meet face-to-face. An ongoing mediation process might also reach a stalemate due to a lack of trust. At this point the mediator can serve as a vehicle to build or regain trust between the conflicting parties. One way to decrease tensions is by finding common ground beyond the conflict (conflicting parties are also parents and may share love for particular sports, etc.) that the mediator uses to bridge the gap between the parties. It is therefore crucial that the mediator strives to detect when the opportunities occur to find common ground.

Third, mediators try to resolve the contested issues between the parties. Hence, there is a set of activities that are issue-related. One of the most important assignments for the mediator is to serve as a 'reality-check' for the sides – a soundboard on what can be realistically achieved. This can be particularly important for the mediator in conflicts where one side is a rebel-group that does not necessarily interact so much with the outside world. Another activity for the mediator is to transfer and transform messages, sometimes technically just handing over messages, but most often interpreting them and trying to frame them in a perspective that can open up the possibilities for more constructive processes. To a large extent, the mediator's assignment is also to chair meetings, thereby systematically walk through the process of what the parties can agree on, as well as what they cannot agree on. The mediator can also help to identify common interests: sometimes there is underlying common ground that the parties are not able to detect themselves (either because they are blinded by negative stereotypes and enemy-images, or because they simply have rational reasons to hide information from each other). In a mediation round the mediator try to detect in which matters the parties' positions do converge and if there are any common subinterest or overriding interests. Whenever similar positions or interests are detected the mediator can use them as a common basis to start building a solution on. In the same line of thought, a mediator might suggest that the contested issues should be handled in a bottom-up process, where the procedural and 'easier' matters (return of refugees, minority rights, etc.) are dealt with and preferably solved before getting to the more difficult matters (independence or autonomy in territorial conflicts, etc.).

Fourth, the mediator handles a set of process issues, which are not related to the issue at stake, but rather relates to how the process should be conducted. It is not unusual that mediators get frustrated by the fact that they get stuck on what can be seen as minor questions, such as in which order the issues of an agenda should be discussed, which points that should be on the agenda, the order through which parties should enter the room, and so forth. For an outside observer, it may seem ridiculous that processes drag on due to these procedural issues, in particular, in situations where delays imply more people killed at the battlefield in the meantime. It might however be a necessary step, dealing with these procedural issues before getting to the main questions. We know that the question of recognizing rebel groups is a difficult problem in internal armed conflicts. Rebels seek recognition through international mediation while governments are reluctant to engage in mediation due to the same reason. Recognition issues are not limited to civil wars, even if they can be particularly difficult in those situations. Even in interstate conflicts, as for instance, the mediation process in war between Iran and Iraq, procedural issues that were intimately related to recognition were extremely sensitive for the parties.

Fifth, the mediator has to take the regional actors into consideration when conducting mediation. In fact, it is not uncommon that the mediator itself is a regional actor, as research shows that in at least half of the mediation cases the mediator origins from the conflict's geographical region (Regan et al., 2009). Regional organizations have also started to engage more frequently in conflict management since the end of the Cold War (Frazier and Dixon, 2006). The reason why regional actors engage in mediation varies. One aspect that might explain this trend is that states risk of getting affected by regional conflicts, and hence will engage in mediation to find a quick solution. First, there is a risk that the conflict will spread to surrounding countries; second, it is usually the closest neighbors that get the largest flows of refugees. Apart from the fear that the conflict will spread, regional actor generally also has political or economic motives to influence the mediation outcome. In order to find a lasting solution, the mediator might therefore have to consult (powerful) regional actors, as it is possible that the regional actor supports one of the conflicting parties and will influence the conflict until it is satisfied with the outcome. Regional actors usually have a greater knowledge about the area and might gain greater legitimacy than mediators without any previous links to the region. Regional actors may thus serve as both an obstacle and an asset to the mediation process depending on how they choose to engage in the process.

Sixth, increasing the costs and benefits of a solution, by affecting the actual situation on the ground (threat of use of force, by themselves, or by others); and increasing the perceived cost of the conflict and the perceived benefits of a solution. Here there is plenty of room for persuasion. The crucial aspect is that the belligerents perceive the threat given by the mediator as a possible consequence or the benefit as an opportunity. As already mentioned, the ability that the mediator has to influence the parties – the degree of leverage – is an important aspect when explaining mediation success. A mediator with low leverage might therefore need assistance from a more powerful actor, which can use its leverage to increase the costs and benefits, by e.g., promising financial support or by threating to use sanctions or military force in order to influence the outcome on the mediation table. A final threat from the mediator can be to withdraw from the mediation process (Höglund and Svensson, 2011).

Finally, mediation does not end with the reaching of an agreement. In fact, different interpretations of how an agreement should be interpreted can cause severe crisis in a post-agreement period. Therefore, conflict mediation will also in many circumstances occur in relation to the implementation of an agreement reached between the parties. To identify the mechanisms through which agreement should be put into reality is an important aspect of the mediators' work. In order to avoid interpretation errors in the implementation phase, it can be beneficial that the reached agreement should be well structured and clearly state the responsibilities for all the parties. This sounds easier than it actually is, as a mediator might have to choose between reaching a somewhat vague settlement, written imprecisely in order to satisfy all the involved parties, or not reaching an agreement at all. It is not uncommon that mediation takes place also after the agreement has been reached, now in the form of implementation-mediation. A written agreement usually cannot capture all the characteristics or solve all the problems that a postconflict society faces – therefore a third party, in the form of peace-keepers, might be necessary in order to maintain the peace.

Mediation Strategies and the Question of Ripeness

This section will discuss two of the main issues in conflict mediation: the question of timing and the question of strategies, and the section ends with a discussion on how these two mediation issues are related to each other. First, let us address the question of timing. An important contextual condition for any serious mediation attempt to be initiated is that the conflict is ripe for resolution (Zartman, 1995, 2003). Hence, the timing of mediation has been identified as important prerequisite for setting the stage for serious attempts to find a resolution to the conflict. The concept of ripeness is not about explaining success in mediation – for a solution to occur there are other factors at play than merely that the situation is ripe. It does however describe situations where there are windows of opportunities: where both sides, at the same time (but not necessarily for the same reasons) are willing to reconsider the war-option as the primary strategy. Due to the inability to make progress on the battlefield, conflict parties are at these moments more open to pursue a negotiated track forward. There are two major aspects of a ripe moment. First, there needs to be a mutually hurting stalemate: the conflict parties are stuck and none of the sides can make any significant breakthrough through unilateral military means. Such as stalemate needs to be incurring costs for the conflict parties, so that they have incentives to move away from the status quo. The other aspect is the more positive one: there needs to be a way out from their predicament, an openness to, and possibility for, a negotiated settlement. One important point to make here is that ripeness is perceptional: it is about the perceptions of the parties (which is, of course, influenced by the objective situation on the ground, but not necessarily the same thing).

In mediation research, three main strategies have been identified, namely the use of facilitative, formulative, and manipulative strategies (Beardsley et al., 2006). The first strategy is the least intrusive – here the mediator merely helps the parties to bring the process forward by themselves, by, e.g., clarifying the situation if the parties reach a deadlock or by transmitting messages between the parties. A mediator engaged in the second strategy, formulation, helps to coordinate the process more actively. This strategy might involve making recommendations or suggestions to the conflict parties or to steer the parties back to the relevant topics, if they start discussing unrelated issues. Manipulative strategies, the most intrusive strategy, involve using carrots and sticks in order to get to a desirable outcome. The mediator might use threats to coerce the parties or promise them benefits if they make concessions. Resent research has shown that formulative strategies are used most frequently by mediators, while manipulative strategies are used the least often (DeRouen and Bercovitch, 2012). Although less intrusive strategies are used most frequently by mediators, powerful third parties have traditionally been seen as the most effective type of mediators (Touval, 1975). Other research points to a completely different finding – the most durable agreements are those that have been reached with little third-party intrusion in the mediation process (Beardsley, 2008). In order to reach a greater consensus on negotiation strategy and successful outcome, one way could be to distinguish between war types. It is reasonable to assume that the intensity and the type of conflict (civil war or interstate war, etc.), will determine which strategy should be used. This is in line with the findings from Bercovitch and Gartner (2006) that high-intensity conflicts are best settled through the use of manipulative and forcing strategies, while fostering strategies are best used on low-intensity conflicts. Another possible conclusion could be that different strategies should be used in different stages of a war. How do these strategies relate to timing? In **Table 1**, there is an attempt to synthesize the main insights from previous mediation research.

Mediation strategies can be thought of in the following way. Manipulation is needed in order to change the objective aspects

Table 1 Conditions of Ripeness and Mediation Strategies – an overview

	Objective ripeness	*No objective ripeness*
Subjective ripeness	Facilitation	Manipulation
No subjective ripeness	Formulation	Manipulation and formulation

of ripeness, for instance, by increasing the actual costs of the conflict. If the conflict parties have the objective but not the subjective aspects, then formulation is needed – there is a need for persuasion, trying to convince the parties that they are in fact stuck in a costly situation and that reaching a settlement is the best way forward. If both the objective and subjective elements of ripeness exists, then the mediator can use a low-key engagement strategy, merely facilitating the process. On the other hand, if neither the objective nor the subjective elements of ripeness is present, the mediator needs to both formulate the benefits of peace and reaching a settlement, as well as changing the objective aspects through the use of manipulation.

Abstract

This article explores the multiple and complex relationships between conflict, education, and youth. We begin by outlining conceptions of education, youth, and conflict, as they vary across legal, social, and physical spaces. Drawing on global examples, we explore the ways education plays a role in instigating, reinforcing, escalating, mitigating, resolving, and preventing conflict. We then examine the psychological, social, economic, and political dimensions of the youth experience and the ways in which they are influenced by living in a conflict setting. Finally, we analyze the role of education in understanding the links between youth and conflict, focusing on access to high quality and relevant education that connects to future prospects for individual youth and their communities.

Introduction

Globally, over 300 million young people below the age of 25 years live in settings of armed conflict (Rahim and Holland, 2006). Popular discourse would have it that these young people are both cause of conflicts and hope for their resolutions. They are described as 'explosive' (Urdal, 2012), as harbingers of violence and threats to stability (Weber, 2013) and 'homogeneous blocks of potential menace' (Talbot, 2011). At the same time, young people have also been at the forefront of leading community and social change (Ginwright and James, 2002) and see themselves as future leaders, preparing to rebuild their communities after conflict.

Despite both destructive and constructive potential, youth have often fallen outside of development priorities and programming, both within countries and on a global level (INEE and Refugee Education Trust, 2013; Robinson, 2011). Educational opportunities for young people have been particularly limited, with attention focused instead on younger children. For example, Millennium Development Goals (MDGs) have targeted educational access among primary-age children, and emergency education as a field is often linked to children's rights and protections (Kirk, 2011). Aid has followed, with only 8% of World Bank lending directed to secondary education compared with 43% to primary education in 2005 (Chaffin, 2010). In conflict settings, only 79% of youth are literate compared with 93% of youth in nonconflict countries (UNESCO, 2011).

Among donors, there is often great skepticism about investments in secondary education when primary enrollment is not universal and postprimary opportunities are more expensive and difficult to coordinate. Staff members of United Nations agencies and NGOs describe how they are required to 'play with the words' and advocate for 'early secondary' and 'basic education and life skills' *in lieu* of postprimary opportunities in order to draw in donors (Dryden-Peterson, 2011b). Funding for education in conflict settings is shockingly low, at around 2% of all humanitarian aid (UNESCO, 2011). Within an already small pool of funds, education for youth is funded at low levels. For refugees, for example, funding for secondary education has been increasing, but it remains minimal. In 2010, it made up only 7% of the education budget of the United Nations High Commissioner for Refugees, however the allocated resources doubled by 2012, to 14% of the budget (Dryden-Peterson, 2011b).

As we look toward the renewal of the MDGs, the education of young people is a high priority. The UN High Level Panel report on the post-2015 development agenda identifies five transformative shifts in order to end poverty and promote sustainable development. The first is to 'leave no one behind' (United Nations, 2013). Despite remarkable progress toward universal education at the primary level, 57 million children and young people remain out of school globally – and 42% of them live in conflict-affected settings (UNESCO, 2013). Compared with other low-income countries, youth living in conflict-affected countries are far less likely to access secondary education. Young people in conflict settings who are poor, female, and from ethnic and linguistic minority groups are multiply marginalized, and they access and persist in school at much lower rates than youth in countries not affected by conflict (UNESCO, 2011).

This article explores the relationships between conflict, education, and youth. First, we clarify conceptions of education, youth, and conflict. Second, we explore the multiple and complex relationships between education and conflict. Third, we examine the psychological, social, economic, and political dimensions of the youth experience and the ways in which they are influenced by living in a conflict setting. Finally, we analyze the role of education in understanding the links between youth and conflict, focusing on access to high quality and relevant education that connects to future prospects for individual youth and their communities.

Definitions

We deliberately draw on a broad definition of education as an intentional learning process. Education, by our definition, can be public or private and include primary, secondary, or post-secondary schooling that is accredited by a government or other body. It can also be nonformal, including catch-up classes, tutoring, or other structured but noncredential-bearing activities organized by individuals or communities.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64120-X

Legal definitions of youth vary across country contexts (Auerbach, 2010). International agencies such as the United Nations tend to adopt chronological definitions of young people as those between the ages of 15–24 (United Nations, 2013). Among researchers, there is increased consensus that youth is a social construct wherein the markers defining the beginning and the end of this stage vary greatly across culture and context (Auerbach, 2010; Clark-Kazak, 2009; Sommers, 2012). Recent analysis of Gallup and Afrobarometer survey data demonstrates that the proportion of youth within the same African nations varies based on the indicators used to define the end of youth and the beginning of adulthood (Mo Ibrahim Foundation, 2012). Programs and policies that adopt legally defined, chronological, and age-static definitions of youth risk ignoring social understandings of youth and remaining disconnected from the lived realities and social complexities of young people. For the purposes of this article, we draw on Clark-Kazak's definition of youth as "all individuals who have passed puberty but who have not yet married" (Clark-Kazak, 2009).

Disciplines and organizations define conflict in various ways. The Uppsala Conflict Data Program defines conflict by the use of armed force and the number of battle-related deaths, with more than 25 constituting a conflict and more than 1000 a war (Department of Peace and Conflict Research, 2014). By this definition, in 2012, there were 32 armed inter- and intrastate conflicts globally, in 26 countries. In this same year, there were six on-going wars (Themnér and Wallensteen, 2013). Here we take a broader definition of conflict, which encompasses acute conflict and war, postconflict settings, and situations of organized criminal violence (World Bank, 2011). We use the term 'conflict-affected' to mean countries that are impacted by violence and armed conflict, resulting in weak governance and inequality in resource allocation that negatively affect the lives and livelihoods of young people and the provision of education (see Mundy and Dryden-Peterson, 2011).

Other terms at use in this field include 'fragility' and 'resilience.' The concept of 'fragility' is often used interchangeably with conflict. The concept of fragility, however, is typically much broader such as in the OECD definition of those countries that are "failing to provide basic services to poor people because they are unwilling or unable to do so" (OECD, 2007). While the term fragility has conceptual value, we do not use it here; the causes and dimensions of conflict are multiple, often contested, and recent evidence suggests that conflict and fragility may have divergent impacts on education (Paulson and Shields, 2014). Largely in reaction to the negative framing of 'fragility,' the concept of 'resilience' is in the process of being widely adopted. This approach recognizes that young people face risks but that they also have assets. A resilience approach to education seeks to minimize the risks, while maximizing the assets for both individuals and systems (INEE, forthcoming; World Bank, 2013a,b).

Connections between Education and Conflict: Multiple Faces

The assumption that education serves as an unequivocally protective factor for youth experiencing the risks and consequences of conflict has dominated policy and programming, until recently. Bush and Saltarelli (2000) instigated a rethinking of the relationships between education and conflict, as they defined the 'two faces' of education: one that builds peace and the other that contributes to conflict. In Sierra Leone, for example, a public education system that was geographically unequal and divided by class may well have been a driver of conflict; redressing the inequalities in this system was one of the central demands of the rebel RUF army in building peace after the cessation of conflict (Novelli and Smith, 2011). Further, educational spaces are often destroyed during conflict and schools transformed into militarized zones, where students are forcibly recruited for participation in armed conflict. Based on the UN Secretary General's 2013 report on Children and Armed Conflict, Save the Children found 3643 incidents of reported attacks against education in 17 countries and 90 cases of military use and occupation of schools in 11 countries (Save the Children, 2013). The 'two faces' of conflict have recently evolved into the 'multiple faces' of conflict, with growing agreement that, more than a fundamental right and a basic state service, education can play a role in instigating, reinforcing, escalating, mitigating, resolving, and preventing conflict.

Several theories complicate the notion that education functions dichotomously toward either peace or conflict. Davies (2011) proposes a 'spectrum of impact' (p. 35) to account for the multiple and intersecting ways that educational actors and institutions can simultaneously do both good and harm. Along this spectrum, educational content and structure both play influential roles and can reinforce or undermine one another. The consequences of unequal access to education can be stark. In 2001 in Nepal, for example, the literacy rate among the ruling Brahmins was 70% compared with only 10% among the lower/excluded castes (Novelli and Smith, 2011). Segregated education systems, such as in Bosnia and Herzegovina, may override curricular messages aimed at promoting interethnic harmony (Torsti, 2009).

Unequal access to education, institutionalized segregation, and lack of postprimary education are overt indicators of structural inequality and often become drivers of conflict. The absence of learning opportunities and the gap between educational accreditation and employment are regularly cited as young people's justifications for joining armed groups (Brown, 2010; Collier and Hoeffler, 2004; World Bank, 2011). Curriculum and classroom practice may also be exploited as weapons of war, taking advantage of education's wide reach and the captive audience of youth at a formative stage of moral and socioemotional development (Pingel, 2010; Spink, 2005; Tawil et al., 2004). Everyday classroom interactions can reveal explicit or subtle discrimination toward particular ethnic, religious, or political groups, even long after conflict has ended (King, 2013). History curriculum is especially vulnerable to politicization. Narratives of historical injustice have been repeatedly manipulated by governments and educational actors in ways that increase social distance between diverse groups, while rationalizing or reproducing intergroup grievances (Bam and Visser, 1996; Freedman et al., 2008). For example, in the former Yugoslavia, history education played a critical role in consolidating citizens' collective identity around histories of ethnic and religious suffering (Torsti,

2009). Some studies of contemporary Israel and Palestine indicate that students are socialized into conflict, normalizing intergroup conflict for future generations (Bar-Tal and Rosen, 2009; Mahshi and Bush, 2006).

In addition to having the power to divide, education can work to create peace and prevent conflict. International organizations and donors are increasingly adopting policies that require attention to the 'conflict sensitivity' of educational programming (INEE, 2013; UNICEF, 2012; USAID, 2013), in order to uphold the principle of 'do not harm.' Further, education may play a role in conflict transformation. Along these lines, education interventions in conflict settings coalesce around the role of education in peacebuilding, violence reduction, conflict resolution, social cohesion, multiculturalism, sustainable development, democratic skills, and human rights awareness (see, for example, Novelli and Smith, 2011).

Recovery from conflict is often an opportunity for building anew, with possibilities for innovation and reform that are more challenging in entrenched systems (Nicolai, 2009). There is a connection between rebuilding the physical structures of education and a perception of trust in a new government, often referred to as 'peace dividends' (see, for example, Practical Action Consulting, Save the Children, & CfBT Education Trust, 2012; United Nations Peacebuilding Support Office, 2012). The content and pedagogy of postconflict education can also work toward peace and the prevention of the recurrence of conflict (Blattman et al., 2011).

Youth and Conflict: Challenging Assumptions

One of the defining developmental experiences of youth is the transition from childhood to adulthood and the identity formation processes that accompany this critical developmental stage (Johnson et al., 2011). Due to the relative lack of tailored services for youth, young people are caught between programming designed for children or for adults, leaving them either excluded and 'on the margins' (Sommers, 2007) or funneled into programs that are mismatched for their developmental stage. Further complicating youth as a target population, legal definitions and culturally specific roles for youth shift (see, Clark-Kazak, 2009), more so in conflict settings than otherwise. In times of conflict, youth do not experience typical childhoods but prematurely enter adult worlds; conversely, conflicts can delay traditional rites of passage and hinder access to markers of adulthood, so that youth cannot become socially recognized adults (Sommers, 2012).

What is the relationship between youth populations and propensity for conflict? There are competing theories. Noncausal empirical research demonstrates that countries with youth bulges and poor economic performance are more susceptible to domestic armed conflict (Urdal, 2006) and democratic instability (Weber, 2013). Two dominant theoretical perspectives have attempted to explain this hypothesis. The first is an economic or opportunity theory approach, where a sudden supply of youth labor in an economic system unable to generate enough jobs and absorb a surge of youth labor supply will render many unemployed. As a consequence, armed groups tend to fill this vacuum by providing alternate income generating opportunities (Brown, 2010; Collier, 2007; Collier and Hoeffler, 2004). The second is a sociobiological approach, where young men (15–29 years), given their developmental stage, are considered to have higher propensities for extremist attitudes and intergroup hate and violence (Weber, 2013). Collier states that "[b]eing young, being uneducated, and being without dependents" may make one more likely to engage in political violence (2007). For some time, these two theories have dominated much of the discourse on youth in conflict, even though researchers have attempted to nuance them, as we discuss below (Beber and Blattman, 2013; Cincotta, 2008; Sommers, 2012; Urdal, 2006).

These theories do not account for three important dimensions of youth in conflict settings. First, they do not account for the agency and resilience that youth exhibit in shaping their life choices even under severe structural constraints and stressful situations (Blum and Blum, 2009). Second, they do not sufficiently illuminate the various ways that education systems interact with youth experience and thus reproduce and/or interrupt conflict. Finally, these theories do not account adequately for the interactions of various social, political, and historical circumstances. For example, in both stable Botswana and conflict-affected Democratic Republic of Congo (DRC), 22% of the population is between the ages of 15 and 24 (Central Intelligence Agency, 2013). Yet these oversized youth populations have not erupted into conflict in both places; while DRC has been engulfed in conflict for more than two decades, Botswana has been stable. A 'youth bulge' combined, as in DRC, with well-established armed groups and a lack of education and employment possibilities can shift the opportunity structure in favor of participating in conflict, over prosocial choices. Similarly, the 'Arab Spring' cannot be considered only a function of a youth bulge but is also associated with stagnating economies as well as corruption and poor governance in many of the countries that experienced these widespread protests (Pollack, 2011). These contexts demonstrate how conflict is embedded in particular sociopolitical contexts and historical moments.

Further theories circulate around youth vulnerability and susceptibility to joining armed groups based on adolescent desires to consolidate their social identity during a critical identity formation stage. Identity threat is among the many drivers of conflict (Novelli and Lopes Cardozo, 2008). Relying on developmental explanations, some argue that in an attempt to explore and assert their identities, youth are easily influenced and conformist in their attitudes, thereby exhibiting greater tendencies toward extremism and recruitment by armed rebel groups (Blattman and Annan, 2010). However, mounting evidence from the field of adolescent and youth development indicates that identity development is progressive and continues even in adulthood. Conceptions of ourselves 'vary along a continuum' (Davies, 2008: p. 187) such that different aspects of identity emerge and change over time along this developmental continuum (Meeus, 2011). This calls into question the sociobiological mechanisms that underpin the 'youth bulge' hypothesis. If identity statuses progress over adolescence and well into adulthood, there is little support for the argument that identity-driven attitudes of inter- and intragroup hatred and violence are not malleable among youth.

Conflict, Youth, and Education: A Synthesis

In examining the role of education for youth in conflict settings, three recurring challenges emerge. First is the limited access to education opportunities. Second is the quality of education, which includes dimensions of content and pedagogy and overall relevance of learning to postschooling prospects. Third is the dichotomous ways in which education can include or exclude youth from community.

Access to education for youth remains a challenge, particularly postprimary opportunities. Seventy-four million adolescents of lower secondary school age are out of school (Robinson, 2011). Lack of access to education is further exacerbated in times of conflict, when children's learning needs are often prioritized over those of youth (INEE and Refugee Education Trust, 2013).

Despite these limited opportunities, the 2011 EFA Global Monitoring Report argued that secondary school is the "cornerstone of education for youth" and that "formal education is the most effective base for developing learning and life skills" (UNESCO, 2011: p. 54). Education for youth is critical, both for individuals and societies. The existence of secondary school opportunities acts as a motivation to enroll in, and complete, primary school (Chaffin, 2010; Robinson, 2011). Further, the economic returns to secondary education are large. At the individual level, each additional year of formal education on average adds about 10% to earnings, and secondary education adds 20% for low-income individuals. The rates of return for secondary education are particularly high in sub-Saharan Africa, at 25%, and in non-OECD Asia, at 16% (Psacharopoulos and Patrinos, 2002: pp. 2, 12). Related, while individual returns to education can be inequitably distributed, the social returns to secondary education are also high: 18.4% in sub-Saharan Africa and 11.1% in non-OECD Asia (Psacharopoulos and Patrinos, 2002: p. 12). In addition, without continued investment in education of youth, the cadres of high-quality future teachers for both primary and secondary education are limited, which poses a major challenge to postconflict reconstruction (Buckland, 2005; Shriberg, 2007).

Education also affords youth opportunities for civic participation and quality of life and, in these ways, it is protective both for individuals and for societies (IIEP, 2011; INEE Working Group on Education and Fragility, n.d.). Education provides youth the opportunity to think about the future (Winthrop and Kirk, 2008) and to imagine what is possible (Martone and Neighbor, 2006: p. 3; Waters and Leblanc, 2005), especially displaced populations such as refugees who have no legal citizenship status. Particularly in situations where entry into the labor market is limited for young people, "they need the stimulus and challenge of education to absorb their energies and lessen their frustrations and anxiety about the future" (IIEP, 2006: p. 2). A 17-year-old Congolese boy who arrived in 2008 in Kyangwali refugee settlement in Uganda expressed the situation this way: "When we reached here in Kyangwali, life became really hard. Because there is nothing to do: in the morning you wake up, you are moving up and down, like someone who is looking to go somewhere but actually you are not going anywhere" (Wettstein, 2011). This sentiment speaks to education both as a process that gives order to the everyday life of young people, and as a pathway that leads to future opportunity.

In seeking to address access to education for youth, recent research highlights the necessity of a focus on the quality and relevance of that education (Dryden-Peterson, 2011a; Robinson, 2011; Winthrop and Matsui, 2013). Indeed, access and quality learning cannot be viewed as a dichotomy. For example, conflict in Cambodia not only interrupted educational attainment levels for the older age groups, but also contributed to subsequently lowering educational attainment rates among their children (UNESCO, 2012). The 2013–14 EFA Global Monitoring Report notes the presence of a global learning crisis wherein 175 million young people globally are unable to read all or part of a sentence (UNESCO, 2014). Quality education is education that is relevant, in that it builds foundational and transferable skills that allow young people to successfully transition from school to work, to build self-reliance, and to contribute to society (UNESCO, 2012).

For youth, there are multiple dimensions of relevance. First, building on a core adolescent need to construct identity through self-reflection and in collaboration with peers, educational programs that recognize the complexity of self-identity as a vital dimension of youth's psychosocial well-being are more effective (Davies, 2008; Meeus, 2011). Second, and related, the content and pedagogy of education can be protective for youth, building physical, psychological, and cognitive health. Drawing from longitudinal research and causal studies, Reyes (2013) concludes that the presence of positive cognitive, social, and behavioral skills in contexts of adversity is particularly protective. In particular, the skills of meaning making, behavior recognition, increased connectedness, and social harmony can enable success in later life. Third, constructing schools in conflict or postconflict settings with the hope of bringing previously divided groups within a shared, common space will fail to achieve its purposes, if youth within these spaces are not working toward a shared goal or learning to negotiate differences among themselves (Davies, 2013). Physical integration is but the first step toward social integration, for which curriculum, pedagogy, and the accompanying teacher training are the central elements (Dryden-Peterson, 2011b; Dryden-Peterson and Hovil, 2004). Experience from Burundi demonstrates that despite constructing extra classrooms, providing school uniforms and scholarships, many youth who were in exile in Tanzania and returned to Burundi remained out of school. The physical infrastructure was in place, but the language of instruction was different from what they were taught in Tanzania, and, consequently, learning remained inaccessible. Additionally, there were social tensions between those who stayed in Burundi and those who returned from exile (Refugee Education Trust, 2012).

The fourth dimension of relevance is the connection between what is learned in schools and livelihoods. A mismatch between skills, job opportunities, and expectations can lead to false hope, breeding immense frustration among refugee young people, and to recruitment into armies and armed militias when that is seen as the more secure livelihood options (Brown, 2010; Sommers, 2006b). In conflict settings,

youth education – especially for young people who have missed out on school as a result of conflict – is often seen as a context best suited to technical and vocational skills development (TVSD). Ideally, TVSD includes both 'hard' and 'soft' skills, "developed within a 'joined-up,' integrated development and delivery framework that seeks to improve livelihoods, promote inclusion into the world of work and that supports community and individual agency" (Conflict and Education Research Group, 2007: p. 2; see also, Lyby, 2003). This kind of training is varied across conflict contexts: among refugees in the city of Kuala Lumpur, Malaysia, it includes baking and computer classes; and, in the context of postconflict Mauritania, there are short (3-week) baking, tailoring, hairdressing, and mechanics trainings (Rahman, 2011; Rezzonico, 2011).

TVSD programs have demonstrated mixed success, can be quite expensive, and in some cases have been dramatically mismatched to market needs. For example, the Norwegian Refugee Council's Youth Education Pack Programme (YEP) is a 1-year full time program focused on literacy/numeracy, life skills, and basic vocational skills (NRC, n.d.). An evaluation in Liberia found that few of the youth trained with YEP could sustain themselves on the income from the new skills they learned in this program; although the skills were relevant to the local economy, the market was oversaturated with YEP graduates and diversification of training was needed (Moberg and Johnson-Demen, 2009). 'Skill mismatch' results from the tendency to train more students every year in the same skills, as in the case where plumbers were trained in Liberia. A former child soldier trained as a plumber reflected: "it's not easy to find work in plumbing, you know? … because most of Liberia doesn't have plumbing" (Conflict and Education Research Group, 2007: p. 13).

The third recurring challenge for education of youth in conflict settings is related to community building. The youth in conflict discourse is dominated by meta-narratives of 'fight or flight' and bellicosity (Clark-Kazak, 2011; Sommers, 2006a) that steer the approaches in conceptualizing learning opportunities for young people. However, causal evidence in the fields of experimental economics and political science finds increased instances of community and civic participation in some postconflict contexts. For example, war victims in postconflict Sierra Leone and Uganda are more likely to engage in their communities through participation in school committees, registering to vote, and in attending community meetings than nonwar victims within the country (Bellows and Miguel, 2008; Blattman and Annan, 2010). Research has established that youth's social connection with their communities can reinforce civic participation, just as increased participation can deepen community engagement (Syversten, 2006). In fact, the drive to find one's niche within society is a fundamental developmental need (Evans, 2007). Yet, many youth across different contexts find a paucity of opportunities provided by their environments (Camino and Zeldin, 2002). In this regard, learning opportunities – formal and informal – serve the role of 'mediating spaces' where youth practice citizenship by exploring what it means to be part of a community, negotiate differences and practice the rights and obligations associated with being associated with a collective (Flanagan et al., 2011). These data suggest that educational institutions are an important space for young people to reimagine themselves, their futures, and their relationship to their local communities, the state, and the global society.

Education programs targeted to former child and youth soldiers often focus on this element of community building (Hansen et al., 2002; Rahim and Holland, 2006). Militias and rebel groups that forcibly recruit young people usually seek to dismantle existing community as a mechanism for compliance and retention, such as when young people are forced to kill members of their own families (Rahim and Holland, 2006). Disarmament, demobilization, and reintegration (DDR) programs seek to rebuild community through education focused on strong relationships, for example. In war-torn Sierra Leone schools created peer supports for youth who had lost their immediate and extended families. This program also played an important role in bringing together former child soldiers and victims (Betancourt et al., 2008). However, education alone cannot integrate former combatants into communities unless psychosocial supports are integrated within the education system to bolster teachers and learners' coping capacities. Some studies of DDR programs (see, for example, Rahim and Holland, 2006) have found that young people demonstrate greater benefits from support structures within their communities than from institutional programming. Demobilizing ex-combatants depends on their capacity to meaningfully reintegrate into society.

Conclusion

The dichotomy of education as a catalyst for or a mitigator of conflict mirrors an underlying set of beliefs about youth's dual role in conflict: that youth are either a problem to be resolved or a solution to be cultivated. Across various fields of study, youth are cast as destabilizers, troublemakers, idle, and criminal, or they are treated as passive victims with stolen innocence (Schwartz, 2010). When prospects for peace emerge, hopes are pinned on youth as the vanguard of the future, and educational recommendations follow suit. Research demonstrates, however, that youth are not confined to these roles, which are outgrowths of the age-old perpetrator–victim divide. Educational policies nevertheless often homogenize youth experience on these somewhat limited and simplistic tropes in order to design educational interventions.

Educational opportunities must consider youth's unique developmental stage and move beyond the victim–perpetrator dialectic in order to maximize the potential for education to mitigate and prevent conflict. Critical elements of education, designed with the needs of youth in mind, acknowledge the central identity-shaping role of coming of age in conflict while at the same time grant young people the agency to define themselves outside of these roles and contexts of violence. Beyond basic skills, schools can provide critical opportunities for youth from traditionally divided groups to make collective and individual meaning of their experiences during conflict, shape new identities, and envision future trajectories.

Challenges remain, even in exemplary cases where educational access, quality, and relevance cooccur. Structural barriers

remain influential, such as the capacities to finance education for youth, access schools, retain quality teachers, determine relevant curriculum, and guarantee basic safety. Those youth who reintegrate in their home communities and seek to change their life trajectories may confront rejection and stigma, even when they are reunited and possess strong social support systems. There are also pragmatic concerns that school learning is disconnected from postgraduation opportunities. Many of these challenges are cross-cultural and resonate across states, even across age cohorts. No matter what context, conflict changes the way that young people relate to themselves, their societies, and their futures. Likewise, conflict shifts how societies envision youth and their roles in creating a postconflict future.

Abstract

This article examines four contemporary treatments of the problem of organizational conflict: social psychological, anthropological, neo-Darwinian, and neo-Machiavellian. Social psychological treatments of organizational conflict focus on the dyadic relationship between individual disputants. In contrast, anthropological treatments take a more socially and historically embedded approach to organizational conflict, focusing on how organizational actors establish negotiated orders of understanding. In a break with the social psychological and anthropological approaches, neo-Darwinians explain the characteristics of organizational conflict by appealing to the concept of natural selection: all forms of organizational behavior, including conflictual relations, stem from the effects of heritable traits associated with a universal human nature. Finally, this article proposes a neo-Machiavellian view of organizational conflict where members of an organization are seen as politicized actors engaged in power struggles that continually ebb and flow.

We make two explicit assumptions in this article. First, a life conducted in, or mediated through, organizations is one of the defining aspects of being a modern citizen. Second, despite the best intentions of some theorists and practitioners, relations in organizations will always entail a degree of conflict and political maneuvering because "[r]easonable people can be expected to disagree on major, uncertain and ambiguously defined issues, and to argue strongly for their personal convictions" (Buchanan and Badham, 1999, p. 21). As a corollary of these assumptions it is likely that we have all been participants in, or observers of, organizational conflict at some time and, in this respect, we may have an intuitive feel for what creates and diffuses conflict in organizations. In this article, however, we adumbrate the key characteristics of the following perspective on organizational conflict: (1) the orthodox social psychology approach; (2) ethnographies of conflict that incorporate the social, cultural, and historical dimensions of organization; (3) neo-Darwinian studies that see conflict as an expression of our essential human nature; and (4) a neo-Machiavellian approach where conflict reflects the politicized character of organizational relations. A general theme of this article is that we should be wary of explaining conflict on the basis of universal or abstract laws of behavior at the expense of a subtle consideration of organizational history and context. (**Table 1** summarizes the four perspectives.)

Organizational Conflict and Social Psychology

Orthodox social psychological approaches explore conflict through a hierarchy of dyadic interactions that start with the interpersonal and stretch to relations between discrete social entities, such as interest groups, unions, and even nation-states. The ways in which these interactions are played out can be mapped using the dimensions of *Process* and *Structure*, thus delineating the two main social psychological models of organizational conflict (Thomas, 1976, 1994). The *Process* model is primarily empirical in approach, as it requires us simply to observe and record conflict as it unfolds. This involves categorizing various generic stages before relating these dynamic circumstances to particular outcomes or 'settlements.' These outcomes tend to be classified in economic terms so that resources – frequently the focus of the conflict in the first place under this approach – are distributed between parties, usually in a zero-sum arrangement. In contrast, the *Structural* model involves identifying the antecedents that shape the dynamics of a particular dyadic conflict. These include cognitive factors (for example, the actors' awareness of issues and possible settlements, their intentions, etc.) and affective states such as emotions and empathy. Underlying the operation of these structural features of conflict is the assumption of bounded rationality: on the basis of the information available to them,

Table 1 A summary of the four main perspectives on organizational conflict

Perspective on organizational conflict	*Basic assumptions*	*Organizational implications*
Social Psychological	Conflict occurs between actors (e.g., individuals, organizational units, organizations, etc.) that are pursuing heterogeneous goals	Negative and pathological if poorly managed Positive and desirable if well managed
Ethnographic	Conflict an epiphenomenon of a negotiated order associated with a specific organizational context	Organizational conflict, a manifestation of local patterns of culture, identity, norms, etc.
Neo-Darwinian	Conflict an unavoidable consequence of our genetically inherited human nature	An organizations should be designed by taking into account the impact of its structure on our inherited human nature
Neo-Machiavellian	Conflict an outcome of the political maneuvring of actors who have varying degrees of political competence	In almost any organizational setting, the outcome of conflict will be shaped, in large part, by the deployment of political skill

actors in a conflict will move toward satisfying outcomes. Thus, as Thomas (1994) suggests, conflicts are decision-making processes that evaluate possible settlements using a combination of rational–instrumental considerations (what in this for *me*?) with normative considerations (is this a 'good' outcome?).

In practical terms, the *Structural* and *Process* models are inextricably bound as the former often provides the theoretical basis for the latter. For example, this implied causal relationship is evident in approaches based on assumptions of bounded rationality such as the behavioral theory of the firm (Cyert and March, 1992) where dividing an organization along, let us say, functional or geographical (i.e., structural) lines creates units that then pursue their own subgoals. This can lead to a commonly observed form of process conflict where it is apparently rational for the units to compete for more of the organization's resources even at the expense of its overall performance (Argote and Greve, 2007). Thus, even at this aggregated level, conflict can be understood as a dyadic relationship involving:

> …a process which includes the perceptions, emotions, behaviors, and outcomes of the two parties. Specifically, in order to differentiate conflict processes from other processes…conflict is the process which begins when one party perceives the other has frustrated, or is about to frustrate, some concern of his
>
> Thomas, 1976, p. 891

Thomas' use of the third person singular pronoun, in generic terms, unwittingly reveals two major assumptions underpinning the psychological approach. First, that we can empirically identify an entity that, much like a self-determining individual, possesses a coherent set of singular, stable, and universal interests, intentions, or affective states. Second, we can also empirically and unambiguously determine these specific psychological characteristics. The effect of these assumptions is to anthropomorphize *all* conflict relations to the extent that, at any level of aggregation, they will tend to follow certain psychological principles premised on the simplest person-to-person dyad. Beyond this obvious conceptual reductionism there are also strong implicitly functionalist assumptions; notably that the normal state for any collective entity is a healthy coherence that will be encouraged by good husbandry of those conflicts that do occur. Such assumptions give rise to the view that, so long as conflict is managed effectively using rational principles, we can keep the lid on organizational conflict and even use it to the organization's advantage.

Thomas (1976) offers three reasons why conflict can be functional for organizations. First, there may be a lack of tension in an organization that can create boredom and complacency while, in contrast, a certain level of conflict may stimulate creativity. Second, the existence of conflicting priorities and, hence, ideas may make for better solutions to organizational problems. Third, aggressive behavior need not necessarily be destructive, especially when it initiates conflict-resolution procedures. Thomas also notes that, as beneficial side effects of conflict, organizations can identify systemic equity problems, address internal power imbalances, and, in situations where the whole organization is united in conflict with another, improve its internal cohesiveness.

Recent theoretical developments have qualified Thomas' proposition, adding further nuances, and today, many conflict researchers work with a conflict topology framework that distinguishes between task conflict and relationship conflict. Much research concerns how task conflict is more likely to be constructive due to its potential to trigger information processing and to lead participants to consider various problem solutions and multiple perspectives. Task conflict may therefore enhance decision-making quality, individual creativity, and work-team effectiveness in general (De Dreu and Beersma, 2005; De Dreu and Van de Vliert, 1997; Jehn, 1994, 1995, 1997; Jehn and Mannix, 2001; Tjosvold, 1991, 2008; Van de Vliert et al., 1999). Conversely, relationship conflict is thought to interfere with performing tasks, thereby lowering effectiveness and innovativeness (De Dreu and Weingart, 2003; Jehn, 1995, 1997; Murnighan and Conlon, 1991) and can have negative long-term consequences for individual health and well-being (De Dreu et al., 2004). Consequently, much conflict research addresses how to reduce those types of conflict that are bad for the organization and stimulate other types of conflict, which are deemed constructive for increasing performance, creativity, and innovation.

The social psychological approach has spawned a whole industry of expert theory and practice that seeks better methods of containing conflict within the limits of acceptability. Generally speaking, however, two main methods of conflict containment are open to us: the resolution of conflict through negotiation or the regulation and minimization of conflict through governance structures. Psychological studies have emphasized the former option to such an extent that the conceptual terrain of organizational conflict is now dominated by ideas of how to negotiate our way out of it! An indication of the importance of this shift of emphasis can be obtained by comparing the entry on 'Conflict' in the first edition of the *Handbook of Industrial and Organizational Psychology* (Thomas, 1976) and the revised entry in the second edition (Thomas, 1994). In this latter contribution the validity of the *Process* and *Structural* models is largely taken 'as read' and most of the space is devoted to outlining subsequent developments in negotiation theory and practice, especially the role played by third-party technocrats in bringing about conflict resolution. Social psychology perspectives typically provide little critical reflection on the adequacy of their models or on the validity of their behavioral assumptions. These shortcomings are particularly troubling: representing *all* organizational conflict as if it took place through the operation of a dyad fails adequately to capture the complexities of the social relations found in organizations. In the light of this, we shall now turn our attention to alternative treatments of conflict.

Ethnographic Approaches to Organizational Conflict

According to Barley (1991), one common misapprehension about the nature of organizational conflict is indicated by our tendency to 'bracket' it. By this, Barley means that we see conflict as somehow being outside the usual day-to-day events of organizational life. It is to be seen as a special case to be treated in special ways. Barley considers this bracketing to be, indirectly, an artifact of the psychological discipline of

conflict and negotiation studies: seeing the world through eyes used to studying dyadic negotiations in laboratory settings predisposes us to look for self-contained conflicts with well-defined antecedents and a limited life span. Barley argues that we need to bring the study of conflict back from the margins and place it at the heart of the quotidian experience of organizations. This means rejecting ideas of utility maximization and individual cognition in favor of anthropology of specific conflict processes; an approach that involves developing an 'ethnography of disputing.' Particularly noteworthy is the use of the term 'dispute' instead of 'conflict.' The change in language stems from a desire to be dissociated from the existing descriptive and normative topologies within the social psychological approaches to organizational conflict. By introducing a perspective on organizational conflict as disputatious, the ethnographic approaches focus on dispute(s) as the unit of analysis to capture the complex interaction of players, issues, context, and dispute processes (Kolb and Putnam, 1992). Accordingly, a disputatious perspective makes it possible to uncover public and private domains of conflict unfolding and conflict management in different settings.

Barley regards the advantages of this approach to be the historicizing and contextualizing of the eternal conflict between organizational actors trying to make sense of their position in a negotiated order. Barley's position relies heavily on the work of Anselm Strauss and his earlier studies of the unstable divisions of labor found in many organizations. Strauss and his collaborators found that, rather than following externally imposed standardized rules and procedures, individual tasks and duties were more the product of bargaining and negotiation between the staff themselves (*see* Organizations: Negotiated Orders).

In general, an anthropological approach to organizational conflict places a good deal of emphasis on the social/cultural context in which the disputants find themselves. These include socially constructed identities (especially 'insider' vs 'outsider' status), the size and complexity of networks of dependency relations, the historical nature of social norms (especially those that define what a 'dispute' is and the rules by which it is handled), and also the resources that actors who are seeking to influence the trajectory of a dispute have at their disposal (Barley, 1991). Overarching these dimensions is an appreciation of the semantic and material implications of the language of conflict; in this way, the anthropological approach shares a number of methodological similarities with Actor Network Theory (Law, 1994) and Domain Theory (Gray, 1989).

The anthropological approach, as depicted by Barley, serves the important purpose of showing us that we do not have to think of conflict exclusively in psychological terms. Breaking the tyranny of the anthropomorphized dyad allows us to think about conflict as a complex nexus of social relations and avoids the functionalist view that it must be doing some 'good' somewhere. Nevertheless, the anthropological study of conflict still remains undertheorized. Indeed, it remains largely an empirical exercise and little theory is at work, an observation that is particularly striking when considering the dimension of power in shaping the antagonistic relations of everyday social settings. For example, Barley's (1991) conception of power extends little beyond the distribution of 'resources' available to parties to influence outcomes in competitive relations, a view that is also evident in some explicitly 'sociological' treatments of conflict (e.g., Tolbert, 1991). Thus, it is little different from social psychological approaches in dealing with the complexities of the power relations mediating organizational conflict. Recently, several authors have addressed this shortcoming in anthropological studies of conflict: for example, Sarat and Felstiner's (1995) application of Michel Foucault to their studies of divorce negotiations. Nevertheless, the general lack of nuance in the treatment of power by theorists concerned with organizational conflict points to an area where studies can be greatly enriched.

The conceptual arena of power underwent profound changes in the late twentieth century, shifting from arid behaviorism to arcane abstractedness, before finally settling into fine-grained analysis (see Flyvbjerg, 1998; also *see* Organizations: Authority and Power; Organizational Control). In part, this shift was symptomatic of a return to a less moralistic and more Machiavellian view of power. We shall return to these themes in the last section of this article.

Organizational Conflict and Neo-Darwinism

The basic premise of neo-Darwinian approaches to human behavior, such as the Evolutionary Psychology movement (e.g., Buss, 2005: passim), is that the human mind is stuck in the prehistoric African Savannah of our hominid ancestors. Behavioral traits – for example, human aggression and a predisposition toward intersubjective conflict – survived because they conferred adaptive advantage on us as a species. Thus, we can establish *ex post facto* explanations for almost any empirically observable form of behavior – on the basis of natural selection then, if it was not adaptive, it would have been bred out. Nicholson (1997) suggests that common characteristics of organizations, such as a predilection for gossip, the love of ritual, and even the existence of hierarchy, can be traced to biologically determined human nature.

The increasing influence of the neo-Darwinian approach (incidentally, a viewpoint that is opposed by many evolutionary biologists who see it as a misappropriation of Darwin's ideas) is already being felt in studies of organizational conflict. For example, it has long been considered that a tension between conflict and cooperation is part of our biological destiny. For example, it has been claimed that, by studying the mutual dependence systems of our hunter–gatherer ancestors, we are able to define a set of desirable social principles for current organizations that are "… more congruent with human nature" (Ehin, 1995, p. 667). Adopting a dualistic model of innate characteristics, neo-Darwinists argue that humans display either *agonic* (aggressive, individually territorial, and hierarchical) or *hedonic* (mutually supportive, group-centered, and egalitarian) tendencies. The extent to which we display one or the other is determined by context and, if we can return to our 'natural' settings, then hedonic predisposition ought to prevail. It is only when we are removed from this setting – in this case, placed in a hierarchy of work organization – that we tend to display agonic characteristics. This position stands as the intellectual equivalent of Hobbes' primitive ruminations and the organizational implications are clear. First, conflict is an evolutionarily advantageous response to many 'unnatural'

forms of organization and, second, if only we can return to a more natural form of organization, then conflict will be, to all intents and purposes, banished as we revert to our hedonic state. This reflects an increasingly popular view that presence of cooperation and the absence of conflict are not just virtuous aspirations within the modern society; they are manifestations of evolutionary success of our species (Pinker, 2011). Not only is this view naive with respect to issues of power, but also a contestable interpretation of Darwin's idea of natural selection. In particular, two specific objections can be laid against it.

The first is fundamental; according to Darwinian adaptation, evolution occurs through random mutation rather than strategic intent and anything that involves intent cannot be explained by Darwinian ideas: in short, evolution is not teleological. Of course, axiomatically this rules out all social situations, including those where parties are in conflict over the relative moral status of competing norms or the distribution of resources. But, as if this misinterpretation of Darwin was not sufficient, such studies can never satisfy the requirements of evolutionary science. This point was made many years ago by de Jong and van der Steen (1998) and has still not been successfully countered. They demonstrate the inability of any psychological study to establish that anything so abstract and socially constructed as a behavioral trait (for example, a predisposition toward conflict) could be advantageous from an evolutionary perspective. Few would deny that heredity plays *no* part in behavior, but it is stretching it beyond the conceptual and methodological bounds of Darwinism to suggest that the dynamics of organizational conflict will be *determined* by human genetics.

A Neo-Machiavellian View of Organizational Conflict

By way of a departure from the previous approaches to organizational conflict, we wish to offer a fourth framework for thinking about the problem. Our starting point is that we must acknowledge that conflicts matter in any organization and we are all players – even in the face of denial or ignorance (being devious or stupid does not disengage one from conflictual processes). There are four basic ways in which the political maneuvring of organizational conflict proceeds. The first three of these invariably lead to protagonists being ousted in conflict. The organizational agent who is not politically skilled will fail. Returning to the Machiavellian theme, the key implication is that skill in the arts of political engagement, strategy, and discourse should be central to organizational competencies.

The first typical mode is to be *in denial* of conflict. We can characterize this as unrealistic, for few rational actors could be insensitive enough to their organizational surroundings to survive in this state for long. Second, there is *passive acceptance without resistance* of what one is in conflict with. This is naive: it accepts what it does not seek to understand or counter. Third, there is *active recognition without action*, where one realizes the nature of the conflict but proposes no strategic counterpoint for dealing with it. We may characterize this as incompetent. Finally, there is *strategic cognition and treatment*, where one recognizes the phenomenon as conflict and treats it appropriately through devising strategies to manage it, with and through the use of power. We may characterize this, after Buchanan and Badham (1999), as developing 'power-assisted steering.'

Essential to these competencies is the ability to be able to creatively improvise around organizational conflicts, through developing a diverse repertoire. This includes image building, selective information release and dissemination, scapegoating of conflictual others, building formal alliances with potential allies, networking with friends and enemies of enemies, striking up appropriate compromises where necessary, being able to manipulate rules, and being ruthlessly pragmatic. Such tactics require deployment in specific organizational contexts, characterized by diverse stakeholders and variable political entrepreneurship. The exercise of power, in ongoing action, will be accomplished through the production of plausible accounts, the creation of viable reputations for political operators, and the achievement of outcomes regarded as 'wins' (Buchanan and Badham, 1999). Essential to these capabilities is a capacity to analyze strategies of power discursively. Those who would be players need to be able to ask questions about the extent to which their power games – actual or projected – will be characterized as ethically acceptable, contextually reasonable, and plausibly accountable? What will the consequences be for those whose reputations are involved in the stakes: who will be weakened, strengthened, or unchanged?

Organizational life involves developing and deploying *political competence*. (The theoretical derivation of this view of organizations are elaborated in Clegg (1989) and Buchanan and Badham (1999).) Sometimes the skill will be in containing conflict or nipping it in the bud, other times ensuring where and when it flares, in what arenas, and with what participants. Conflicts represent opportunities for honing the skills of political competence in whatever normative order the organization constitutes. Clearly, these are highly variable – but even the most sacred may be as readily characterized in these terms as may be the most profane – as any reader of Trollope's '*Barchester*' novels could attest. Political strategy does not depend on the normative environment in which it is lodged so much as the strategic capabilities deployed. On this reading, Machiavellian skills are appropriate in any organizational context.

Conformity: Sociological Aspects

Abstract

Conformity is a central feature of social life. There are three main approaches to conformity in the social sciences. One stresses the role of psychological motives that lead to similar behavior. The second insists on the existence of a social level that would exert pressure on individuals. And the third describes the role of reasons and justifications, in various situations, in order to interpret conformist attitudes. The article will explore the ways those various approaches interpret social conformity. It will do so however by distinguishing three main fields where social conformity arises: first factual beliefs; second, the moral, political, and religious rules and norms which strongly encourage or forbid certain attitudes; third, lifestyle or cultural attitudes, including food, language, aesthetics. The article's main point stresses that the very formal notion of conformity disguises various problems when the specific fields of action are taken into account.

The concept of conformity in sociology has a very large scope due to its sheer formality: it can be applied to any social behavior and belief when it is considered from the point of view of its frequency within a group. This article examines the typical situations, constraints, and motives that lead to similar or dissimilar behaviors, which are more or less strongly reinforced by different types of sanctions or rewards. There are three main approaches to conformity in the socials sciences. The first stresses the role of psychological motives that lead to similar behavior. The second insists on the existence of a social level that exerts pressure on individuals. And the third describes the role of reasons and justifications in order to interpret conformist attitudes. The reasons depend on beliefs and justifications on one side, and on circumstances on the other. These justifications and circumstances differ according to the variety of fields of action. Three main fields where social conformity arises can be distinguished: first the positive beliefs; second, the moral, political, and religious rules which strongly encourage or forbid certain attitudes; third, lifestyle or cultural attitudes, including food, language, aesthetics. The article's main point stresses that the very formal notion of conformity disguises very different problems when the specific fields of action are taken into account. For instance, conformity can be opposed to deviance and to innovation altogether. But deviance and innovation are certainly not equivalent.

Three Models of Conformity

Conformity depends directly on the degree of similarity between an individual action and another, those actions being more or less frequent in a group. But in addition to this frequency aspect, there is a sense of obligation linked to the idea of conformity: people feel more or less obliged to act in a certain way. There are therefore in any conformity phenomenon three dimensions: the object of conformity (a given attitude), the sense for a given individual that he or she should adopt this attitude, and a diffuse pressure among people to force each other to adopt this attitude. Whatever its origin, conformity is always strengthened by unequally strong positive or negative rewards and sanctions. From death penalty to intellectual dissatisfaction, from imprisonment to snobbery, conformity is most often reinforced by social sanctions in different ways. Sanctions are at the same time a cause and an effect of conformity, since the belief that social norms should be followed will lead to the setting of sanctions for deviants; and the sanctions tend to reinforce the respect of norms.

Yet it is also observable that conformity can occur when no sanction at all is observable, for instance in the case of people's breakfast habits, which largely differ from one society to another, this difference being related to a group attitude. However, even in this case, people tend to believe that this attitude is the 'best' one for them, inside their group. The link between the selected attitude, its choice by an individual, and the social pressure to conform to it is the existence of a norm that prescribes a certain type of behavior for the members of a group.

In this respect the size of the reference group in which the norm should prevail can have a variable extension (Mead, 1962): for a Catholic, or a believer in human rights, humanity as such should comply with some specific norms, whereas the follower of an elitist fashion will stop liking it when the number of followers has reached a certain size (Coleman, 1990). However, people can belong to several groups at the same time, each of them being submitted to norms, that can be consistent or opposed: for instance gay people can be catholic believers at the same time, the catholic church being globally opposed to homosexuality. This is not a pattern of modern societies alone: in traditional societies, people can belong simultaneously to various groups, depending on their religion, work, family, or language (Gellner, 1983).

There are basically three models in the social sciences literature to interpret such conformity. The first one is mainly psychological. It stresses unconscious trends toward social conformity. The second one, rooted in Durkheim's theorization of society, insists on the role of a specific social level that exerts coercion on individuals. Finally, the focus on rationality will specify the reasons for which people adhere to norms and therefore display conformity in adopting them. The rational approach has itself two sides: one is utilitarian and is based on cost benefit analysis. The other one stresses, more broadly, the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.32027-X

reasons one has to adhere, in a given situation, to specific beliefs or attitudes. Since those reasons, in given circumstances, are shared by individuals situated in similar social situation, this raises conformity.

The first model can be historically related to Tarde (1962) who stresses the importance of imitation to explain similar behaviors in social life. Imitation appears to him or her as a constant attitude, which explains all social phenomena: all fields of action are involved, and innovation, or dissent, depends always on previous imitations. In contemporary psychology or anthropology such a trend (mainly unconscious) toward imitation is frequently described as a key element toward the diffusion of common patterns of behavior (Sperber and Hirschfeld, 2004). It leads sometimes to a decidedly irrational explanation of the adoption of group attitudes (Haidt, 2012) based on evolutionary selection of behavioral patterns. People do not choose conformity on the basis of an individual choice, but because there are unconscious selected motives that lead them to do so.

Durkheim (1982) does not accept this rather general idea of imitation based on psychological motives. There is indeed for him or her a similar strong social tendency toward the building of common patterns of behavior: moral, religious, linguistic, or esthetic rules express in a common way the fact that society is built up on the necessity of integration of individuals throughout shared values. Despite any subsequent difference of attitudes, conformity is an essential feature of any society. It stems from a sense of oughtness shared by the members of a group: they all feel that they should behave in a certain manner. But whereas Tarde originates this sense of conformity in a psychological trend, Durkheim locates it in a specific social level. This social level can be interpreted in two different dimensions. First, it would be a specific social reality that exerts pressure on individuals, but this leads to ontological problems, since it is not obvious that such a social entity exists as such. More modestly, the social level will refer to the fact that a norm is always social, and its respect is always the result of an interactive reinforcement: it is not a lonely attitude.

With the notion of rationality, a third approach is introduced, which is not strictly psychological, nor 'social' in the durkheimian sense. The notion of rationality is a key element to understand conformity in a social world. It stresses either the interests someone, in a situation, has to adopt a norm; or, more generally speaking, and beyond narrowly selfish interests, the reasons someone has to adopt a norm. For sure, it can be said that compliance with norms is not necessarily directly conscious: it can even be difficult for people who follow a norm to give an accurate reason for why they do so. This is true of any behavior, and already been noted by Weber. This is also a key element of the psychological literature about norms compliance (Haidt, 2012), which stresses in a more radical way that justifications are only attempts by actors, ex post, to find reasons for behaviors that are not at all in fact determined by reasons, but by instinct and emotion. However, norms acceptance is often linked to conscious reasons that justify it. Conformity is related to beliefs and to justifications: people are conformists or deviants because they believe they should be so, and others are asked to behave in the same manner when they are thought to belong to the relevant group to which the norm that introduces conformity should apply. Therefore, a study of the conformity problem must include a study of the typical motives for which a justification is commonly accepted or rejected.

People most often obey a norm because they believe the norm is valid. They can also obey the norm because they are forced to comply with it, without accepting its validity. It can happen also that the members of an interaction follow a norm because everyone believes that the others want him or her to respect the norm, although everyone would also prefer not to do so. The result is paradoxical: everyone follows a norm (for example, heavy drinking habits among college students) whereas everyone would prefer not to do so (Willer et al., 2009).

Symmetrically, actors can refuse to obey a norm not because they do not acknowledge the validity of the norm, but because they have occasionally a stronger interest against its following. On the other hand, people can refuse to obey a norm because they believe it is unfair, or useless, or unnecessary, or inadequate: people may think that a norm is illegitimate from the point of view of their position in society. For instance, those who cannot through their personal effort achieve a social promotion will tend to believe that, since they do not have such opportunity, they cannot have any faith in a social order that builds its legitimacy on this very self-promotion through effort (Merton, 1957). Those conditions can be related to the position of an individual within a group, or to the members of a group within a larger group.

In sum, it can be said that in order to interpret social conformity, there are mainly three dimensions that should be taken into account: the psychological motives that lead to conformity; the social pressure that exerts conformity; and the reasons people have collectively to display conformity. Sometimes these three approaches can be contrasted. However, they can be seen as well as complementary, since any conformity phenomenon involves at the same time psychological motives (the fear for instance of losing one's reputation), social pressure, exerted through interaction, and reasons, in given circumstances, to adopt a belief or a norm. This interconnection can be seen in the various fields where social conformity arises.

Positive Beliefs

A first domain for conformist attitudes is that of positive beliefs. The very idea of 'positive' beliefs, that is free of any normative content, is a creation of philosophical and sociological tradition, when it stresses the difference (and sometimes the opposition) between facts and values. Moreover, sociology has described a historical evolution tending to separate positive beliefs from normative ones: it is one of the dimensions of the long run social process conceptualized by Weber as rationalization. The distinction between fact and value can certainly be contested (Putnam, 2002). Moreover people in current social life most often do not make such a distinction, and would maybe reject it. However, it is clear that people tend to have positive beliefs regarding specific facts, and that those beliefs do not correspond to an approbation or

disapprobation of these facts. In this field there are strong claims to conformity based on epistemic norms that are supposed to have a universal validity.

These norms are related to the norms of rationality that should impose on rational people to hold accurate beliefs given the information they have access to. Conformity derives in this case from common cognitive features that enable people to have correct statements. Rationality can be attacked in this respect in a radical constructivist or culturalist way that would deny the existence of intrinsically valid universal norms. However, it seems hard to avoid a notion of correctness based on rationality to interpret at the same time common social attitudes and beliefs, and science itself (and sociology in particular).

However, in this positive domain, there are frequent errors. The very notion of error presupposes correctness, and therefore a notion of rationality. Psychology will tend to stress the importance of three kinds of factors in explaining such typical errors. First, people can make errors because they do not have access to the correct information, or because they try to solve difficult problems with limited cognitive effort or abilities: they reason too quickly (Kahneman, 2011). Second, people can have false beliefs because they have some motivation, interest, or desire to hold them (Gilovich, 1991). These two dimensions are not social as such, although they can be widely diffused in social life. But there is no direct role of social interaction in these cases. However social psychologists have also experimentally studied the conditions under which conformity arises from specific social settings: it is proved that it is difficult to go against commonly held opinions, even when the actor has the means to recognize that they are erroneous (Asch, 1956; Sherif, 1972).

Generally speaking, people can hold false beliefs because their social environment supports such beliefs, and therefore others influence people in their opinions. Conformity arises in this case from the fact that one's opinion is not forged in loneliness, but depends on others' opinions on the subject. Tocqueville (1966), for instance, explains that people need general ideas to achieve their ordinary actions, but they do not have the means to verify the validity of all the beliefs they will refer to. In a society based on the dismissal of all authority, the majority of people will think that the most acceptable belief is the one that is commonly shared by others. There will be a tendency toward conformity since the adoption of majority's voice is less costly, both from an intellectual point of view and from a social point of view. The role of ideology can thus be very strong, based on the mixture of false beliefs and social reinforcement of those beliefs: since dissent is costly in a situation where a belief is widely shared, it will be minored. Dissent is costly in two different ways: first if others want you to believe something, and will oppose you if you do not share this belief, someone can be criticized or rejected and suffer this isolation. Secondly he or she will have to justify his or her beliefs: it can be difficult for someone to defend his or her opinions against all others. This is why generally dissent does not occur between one individual and a group, but between groups, inside of each of them everyone feels he or she is supported by the belief that others share the same attitude.

Social Rules in Moral, Political, and Religious Fields

As previously mentioned, conformity often implies a problem of legitimacy, although people are not necessarily capable of giving the reasons for which they follow a norm. There are strong social norms regarding social practices in moral, political, and religious fields. The aim of those norms is precisely to impose conformity: they prescribe and proscribe various behaviors and attempt at homogenizing them. The content of these norms tend to vary in a significant way from one society to another, and there is also a historical change that must be taken into account. Sociologists often consider that this variety must lead to a complete relativity of values. That would be a culturalist point of view, derived from anthropology. Conformity is inherent to social systems, but the heterogeneity of norms is a fact that cannot be reduced to any deeper unity. This view can be supported in a positivist tradition by the fact–value dichotomy: it would express that values cannot be vindicated, and are therefore arbitrary (Pareto). There is a war of gods (Weber).

However, it seems that there are four relatively constant norms throughout all cultures (Cusson, 1983): incest between mother and son, father and daughter, or brother and sister; rape of married women; murder, meaning the voluntary act of killing someone who belongs to one's own group; theft. Of course, the last case is the less accurate since the definition of legitimate belongings can vary in such a way that property itself can be seen as a theft. But these common features are a very small part of all the social norms linked to conformity.

Independently of any kind of intrinsically justification of norms, and beyond their constancy or variety, conformity can be then interpreted in terms of power and interests. The common adoption of norms can derive from a common shared interest in adopting them, which leads to conformity; alternatively some people can impose norms to others in a power relationship, where the interests or the ones are realized at the expense of the interests of the others. More rarely, norms exist that do not correspond to the interests of anyone: many taboos are of this kind, where the norms prohibit some kind of actions, without any kind of advantage produced to anyone (Elster, 1989). It can happen also that, although everyone has an interest in changing a norm, the coordination costs to achieve this change are too high, and therefore the inefficient norms remain.

Conformity can derive from a situation where people have a common interest in adopting a norm. This is the case for instance when people must decide whether they should drive on the right or the left. Once a norm has been selected, everyone complies with it because no one finds an interest in deviation from the norm. A more complicated choice occurs in a prisoner's dilemma situation. In this case, everyone would like others to follow a norm, but has an interest in cheating regarding this common interest (Coleman, 1990). In this case, either the norm emerges, and conformity arises from a common observance of its requirements, or it does not emerge, and people loose the benefits of cooperation. Conformity can derive from the respect of the norm, or from its nonrespect (everyone decides he or she should not respect the norm because he or she believes that others will equally

not respect it). Processes of effective emergence of norms are complex ones, and imply various circumstances and actors.

But interests can lead equally to relations of power and domination. Economists and sociologists have explored these situations. For instance, in institutional economics, so-called 'natural orders' are described as places where elites impose specific rules that favor them to the detriment of others (North et al., 2009). The norms resolve at the same time the problem of violence: but they do so by favoring some individuals at the expense of others in stable hierarchies. This does not necessarily lead to a sense of conformity, since people tend often to challenge these norms, and the fact that they are imposed at one time does not make them legitimate in a permanent way. Therefore the evolution of norms depends on the evolution of the equilibrium of powers inside a society.

Sociologists have equally insisted on the existence of norms favoring some at the expense of others. This can lead sometimes to a sense of conformity. Many labeling theorists (Becker, 1963) interpret conformity as the result of a power relationship: the powerful impose on others conventions that are arbitrary. Arbitrary conventions have two effects. Firstly, some people are labeled as deviants whereas others are praised as conformists. This expresses the structure of power in society, not an intrinsic validity. Secondly, once people have been labeled as deviant, this label reinforces by stigmatization their deviant situation, since others can no more accept them as nondeviants. This narrows the range of actions that are available to them; eventually the stigmatized can themselves believe that they are deviants. In this case, we have a psychological mechanism, based on social power asymmetry, where people might accept an arbitrary norm that is exerted to their detriment.

When there is an asymmetry of power, some people tend to impose on others a norm that depends only on a power relationship. But at the same time, people tend to impose norms that they often believe to be legitimate. For instance, it is clear that racist norms appear in slavery situations. When people have an interest in having slaves, they also tend to believe that they have good reasons to be a racist, and will consider the inferior traits of the oppressed as 'natural' features that deserve subordination, instead of realizing that these traits are precisely an outcome of the subordination (Douglas, 1986). The victims themselves might then believe sometimes they are intrinsically inferior.

But this scenario is not always the prevalent one. The stigmatized can claim and vindicate a change of norm that is the replacement of a nonvalid norm for them by a valid one. Moreover, independent observers will tend to have a more independent point of view. For instance, critics of racism will support the idea that there is no legitimate ground for racism, and they will try to set up a norm against racism (Appiah, 2010): when they succeed, racists become deviants. If labeling theorists maintain the idea that there is never any intrinsic value to certain rules, they will have no basis for the replacement of a racist rule by a nonracist rule, and they will treat in the same manner the deviant who does not accept a prevailing racist norm and the deviant who does not accept a prevailing nonracist norm.

Therefore, historical change must be taken into account as it can be in part related to the relative strength of different arguments regarding norms. If we consider, for instance, norms regulating sexual behavior, Christian religious belief tends to condemn, on a metaphysical basis, premarital sex, divorce, homosexuality, and pedophilia altogether. This is not directly linked to the interest of a category of the population exerted at the expense of the others. It is a moral representation based on religious beliefs (and maybe independent sexual taboos). But in a society where people are submitted to such norms, when they do not share the religious beliefs, they might consider themselves as victims of arbitrary norms. In such an instance they might believe that they have a right to do whatever they wish to do, in spite of those forbidding norms. It can be noticed, therefore, that when there is no more consensus on religious norms for sexual behavior, the only path usually found to maintain a legitimate norm that will be more or less accepted by everyone will be to refer to the principle of personal choice. Religious people will act according to their choice, and the nonreligious to their other choice. Modern societies thus increase the principle of personal choice, and diminish the authority of traditional or religious norms. The change is significant: premarital sex becomes the norm, divorce tends to be widely practiced, and homosexuality is increasingly legalized. But one significant aspect of this evolution is that norms against pedophilia tend on the opposite to be strengthened in such a society. This is easy to explain since, on one side, divorce or homosexuality are related to a freedom of choice among consenting partners. If a marriage is a contract between two adult persons, the notion of agreement can imply that the contract should be dismissed if the two partners do not agree any more, even if this is considered to be a failure from another point of view. On the contrary, pedophilia is definitely rejected because it involves children, legitimately seen as victims because of their lack of choice in such circumstances of abuse.

Therefore it cannot be said that a labeling theory is the last word on the problem of conformity or deviance. Both depend on beliefs and possibilities of legitimacy. In other words, norms can be said to depend on reasons. In this case, if strong norms depend on religious beliefs, when they are imposed on others who are nonbelievers, there is a problem of legitimacy if those beliefs cannot be proved to be right or wrong. Therefore, rationalization will tend to lead to a situation where such norms will apply only to believers. In this case, the principle of choice tends to legalize some practices, and to reinforce the fact that others are forbidden.

According to Boudon for instance (Boudon, 2001), we can try to find the reasons for the acceptance or the rejection of a norm, given the social situation and information of actors. Dissatisfaction can occur when there is a rejection of the elements on which the norm is based, or when the norm can be seen as valid in general, but not in the situation where the actors find themselves. Once again, for instance, according to Merton's description, someone will tend to reject a social order based on the idea of self-promotion through effort when it cannot be really achieved. Here a problem of consistency is faced: the norm is valid under certain conditions, but ceases to be so when those conditions are not met.

Hence, conformity should not be seen as static. Many norms depend on beliefs that are submitted to change and rationalization. One of the aspects of this rationalization is that

some norms cannot be valid to certain people: for instance, if there is a norm supporting slavery, it will tend to be withdrawn in the long run since it is inconsistent with the source of any legitimacy for individuals, their ability to accept a norm, which implies a certain amount of freedom of choice. Some norms are seen as oppressive which were not before, because the belief on which they were based is no longer shared. From a rationalistic point of view, there can be a discussion that shows that conformity or deviance depend partly on the perception of the validity of norms. It can be said that norms tend to be rejected in four major cases: when they just express a power relationship that is disguised in some other value; when they are grounded on false beliefs; when they are grounded on beliefs that cannot be proved and which have no self-evidence – in this case, they cannot be imposed on someone who does not share such beliefs; finally, a norm is not valid when it cannot be applied to someone's situation.

Norms of Culture

In the two previous sections, I have tried to isolate norms that can be discussed among people from the standpoint of their validity. But there are other norms that are connected to strong conformity that do not seem to be negotiated in terms of validity. For instance, Japanese women tend to walk in a way significantly different from European women. On one hand, there is no obvious reason to consider one way as better than the other; on the other hand, such behaviors express conformity, since they are group behaviors. How should we give an account of such attitudes applied to food, language, dress, architectural habits, etc.?

Three major elements can be stressed regarding this type of conformity. First, it can be related to practical constraints. A language must be shared among people to be efficient for communication. Here, conformity is just the result of the nature of the practice. There cannot be a private language (Wittgenstein, 1967).

Second, similarity can express integration to a group. For instance, it is obvious that religious dress is linked to the sense of belonging to a community, which can be turned into strategic devices. People tend to adopt some features to show that they belong to certain groups (Simmel, 1923). This can be done because belonging to a group is seen as important, or because belonging to a group is a consequence of a common faith or a common goal, or because there is some sort of distinction that is looked for (Veblen, 1953).

But finally, it must be said that in these fields conformity tends to be linked to innovation. It is obvious in the esthetic field: on the one hand, there is a huge amount of conformity that is observable in the constituency of local schools, such as the general use of Romanesque architecture during certain periods in Europe. This conformity, however, does not exclude innovation; Gothic style sooner or later replaces the Romanesque. It would be too difficult in this article to assess all the elements that play a role in such an evolution. It is clear at least that the previous ones are important: interactive constraints, and the sense of belonging to a community. But these allow the evolution of behaviors and the place for innovation.

Congress: United States

Abstract

The United States Congress is distinctive among national legislatures in the world in that it is extremely powerful in legislating and policymaking. It is characterized by a system of committees that structure much of the legislative process. Members of Congress enjoy substantial incumbency advantage, and enjoy significant independence from national party leaders. Both the House and the Senate are characterized by complex internal procedures that have an important impact on legislative outcomes. An important recent development in Congress is an increased polarization between the major political parties.

The United States Congress is distinctive among the world's legislatures in its independence from the executive, its complex internal organization and procedure, and a capacity to develop its own legislative proposals. Senators are elected at large from their states, while representatives are elected from single member districts. The use of primary elections to make party nominations gives members of Congress a substantial measure of freedom from the leadership of their party, but makes them beholden to their district. Because of a substantial 'incumbency advantage' – due to advantages in fund-raising, and other factors – members of the House and Senate are reelected at very high rates. Internal structure of both the House and Senate is dominated by two institutions: parties and committees. Committees have great influence in shaping legislation and in determining what legislation will reach the floor. The majority party has much responsibility for organizing the agenda of Congress. The rules of the House of Representatives are designed to allow the majority to prevail, so they place strict limits on debate and amendment. The smaller Senate allows far more freedom for debate and amendment. The president has influence over members of Congress, especially those from his own party, but even members of the president's party are strongly influenced by their constituencies.

For much of the twentieth century the political parties in Congress were not sharply distinguishable, exhibiting considerable overlap – often to the regret of partisans. In recent decades, the Democratic and Republican parties in the House and Senate have become much more polarized. By some measures Congress since 2000 is more polarized than ever before.

Among the world's national legislatures, the United States Congress stands out as far and away the most powerful. It is distinctive in its independence from the executive, its complex internal organization and procedure, and a capacity to develop its own legislative proposals.

Congress is composed of two chambers: a Senate, in which each state has two senators; and a House of Representatives, in which the number of representatives from each state is determined by population. There are 100 senators and 435 representatives. To become law, bills must be passed by both chambers and be signed by the president. Bills vetoed by the president can become law, provided two-thirds of both the House and Senate vote to override, but that is rare. Senators are elected for 6-year terms, with a third of senate seats being filled every 2 years. Representatives are elected to 2-year terms, and all come up for reelection simultaneously.

Congressional Elections

Senators are elected at large from their states, while representatives are elected from single member districts (*see* by contrast, Proportional Representation. Also *see* Elections: Apportionment). The 2-year terms of Representatives are the shortest term of any national legislature. The authors of the Constitution intended the House to be the 'people's' chamber, and meant to keep them on a short leash. The 2-year term does this most effectively. Members of the House are for practical purposes always running for reelection, and they must constantly pay attention to constituency concerns. Indeed, it is widely accepted that the desire of members to be reelected has a vast influence on congressional structure and policymaking (Mayhew, 1974; King, 1997).

Gerrymandering

Senate 'districts' are the entire state, but House districts are each a subset of a state, devised through a political process (except for state that have only one House seat). States legislatures pass laws every 10 years drawing new district lines such that each district within the state has an equal population. The lines demarcating districts are often drawn to accomplish political purposes, a practice known as 'gerrymandering.' The purposes of gerrymandering include protecting incumbents, advantaging one party at the expense of the other, and promoting the election, or defeat, of racial and ethnic minorities. Gerrymandering commonly results in bizarrely shaped, buglike districts.

Primary Elections

In nearly all places in the United States, party nominations of candidates for Congress are done by means of primary elections, not by party committees or conventions. In other words, the national party organizations have little influence over who runs for Congress under their banner. This system provides members of Congress with a degree of freedom from their

national party leaders not enjoyed by members of the European parliaments. They must, however, satisfy the party activists in their state or district who tend to dominate primary elections.

One culprit allegedly responsible for increased polarization is a rise in primary challenges to incumbents. Several prominent and successful challenges to incumbents since 2000 have left a widespread impression that greater polarization of the electoral base has prompted more ideologically based challenges to incumbents, and this threat is driving members of the House and Senate away from the political center. The Tea Party movement in the Republican Party is seen as particularly responsible for this development. Boatright (2013) finds little evidence to support this thesis and contends that in fact primary challenges are not more common than in prior decades.

Incumbency Advantage

Members of Congress enjoy a substantial 'incumbency advantage' that enables them to be reelected at high rates. Typically, 90% or more of House incumbents who seek reelection win. Senate incumbents are somewhat less successful, but still manage to be reelected with great regularity. Even in elections featuring higher levels of turnover such as 1994 and 2010, nearly 90% of incumbents seeking reelection to the House are victorious. Even including voluntary departures from the House by retirement, normally 80% of the previous House is reelected. Incumbency advantage stems from the greater name recognition that incumbents enjoy compared to challengers, from their ability to do favors for constituents, and, perhaps most importantly, from their superior ability to raise money to finance their campaign. Congressional campaigns have become extremely expensive in recent decades, with the victorious House incumbents spending on average $1.5 million in 2012, and victorious Senate incumbents spending on average $11 million (*see* Political Money and Party Finance). According to Jacobson, there is a self-fulfilling quality to the high reelection rate of congressional incumbents. The seeming invulnerability of incumbents, and the daunting challenge of raising the money necessary to mount an effective challenge, discourage many would-be challengers, leaving incumbents to face incompetent, underfunded challengers who have little or no chance of winning, thus further inflating reelection rates (Jacobson, 2012).

Internal Organization

The United States Congress has a complex internal organization that has a great influence on how it translates the preferences of its members into legislation. Congressional organization is dominated by two partially competing institutions – committees and parties. Congress emerged more or less in its current, modern form at the end of the nineteenth century by means of a process of institutionalization (Polsby, 1968). Boundaries were established as once rapid turnover declined; internal complexity developed as standing committees became more firmly established; and universalistic decision-making criteria developed as seniority took hold.

Committees

Both the House and the Senate have a set of standing committees with fixed legislative jurisdictions. Normally, all legislation, once introduced by a representative or senator, is referred to a committee with jurisdiction over its subject matter. All members of Congress are assigned to committees. Senators have three or four committee assignments, while representatives have one or two. The party organizations in Congress make assignments to committees, but generally members are placed on committees where they have some interest. Some committees have more important jurisdictions than others and members naturally seek to be assigned to those committees. Seats on committees with jurisdiction over spending and taxation are among the most sought after, and the hardest to get.

Committees have great influence in shaping legislation and in determining what legislation will reach the floor – a bill is seldom considered by the entire House or Senate chamber unless it has been recommended favorably by the committee with jurisdiction. Committees do not have the power to force Congress to adopt legislation that its majority does not prefer, but they can block legislation a majority would favor, and thus they serve as an important veto point in the legislative process.

In both the House and the Senate, the chairperson of each committee is normally chosen according to a norm of seniority, whereby the member of the majority party with the longest continuous service on that committee is selected as its chairperson. The seniority norm is violated occasionally, especially when the majority party has just experienced a large influx of new members who have little commitment to seniority. This was the case in both 1975 and 1995, occasions on which the seniority norm was violated in three instances. Since 1995, there has been a declining commitment to seniority as a means of choosing committee chairs. Seniority has been partially replaced as the criterion for selection as a committee chair by fund-raising efforts on behalf of the party and ideological agreement with the party (Cann, 2008).

There is substantial debate among scholars about the consequences of delegating power to committees. One view holds that, because the members of a committee may not reflect the views of the entire chamber, they write legislation that advances their own interests, and not those of Congress as a whole. Another view holds that the chamber as a whole would not allow itself to be cheated in this way, and has effective tools to keep its committees in line and working for the benefit of the whole institution (*see* Delegation of Power: Agency Theory).

The committee system of Congress is commonly believed to strengthen Congress vis-à-vis the executive branch by encouraging its members to specialize. As issue specialists, members of Congress can better resist the executive branch, develop their own legislative proposals, and transform proposals submitted by the executive (Polsby, 1975).

Party Organization

Nearly all members of Congress belong to the Democratic or Republican parties. Party is an extremely important aspect of

congressional action, but political parties do not command the same degree of loyalty in Congress that they do in most other national legislatures. Party leaders in the House and Senate have a great deal of influence over the agenda, helping to determine what legislation will come to the floor, and when.

Recent party leaders have been motivated by varying conceptions of the leader's role. Newt Gingrich, Speaker of the House from 1995 to 1998, saw it as his responsibility to articulate a vision for the Republican party and he expected his party to follow him. This was an unusually expansive notion of congressional party leadership that his party was not willing to support indefinitely. In 1998, unhappiness with Gingrich's leadership resulted in his ouster. His successors, Dennis Hastert and John Boehner, both Republicans, and Nancy Pelosi, a Democrat, have returned to a more traditional leadership posture of seeking to identify a set of positions that unite his party and endeavoring to pass bills that accomplish those purposes. Parties and their leaders sometimes try to enforce party discipline by threatening wayward members with loss of committee assignments, chairmanships, or loss of other perquisites, but this is unusual, and sometimes drives dissidents into the waiting arms of the other party. The leaders' job might be better described as discovering rather than creating an agenda for the party. In 2013, Speaker John Boehner found himself the subject of an unsuccessful attempt to defeat him for reelection as speaker. The campaign against him was orchestrated by members of the Republican Party who found Boehner too accommodating to President Barack Obama.

The power of party leaders is limited by the willingness of party members to grant them power. With the members of Congress always eager to appeal to their own unique states and districts, they are reluctant to grant party leaders much power, for that might limit their own ability to pursue initiatives beneficial to their constituents.

To a substantial degree, the power of committees and party leaders is contradictory. To the extent that party leaders are able to increase their power, they do so at the expense of committees and committee chairs. When party leaders seek, as Gingrich did, to determine themselves what the agenda of the House will be, and what legislation will look like, they arrogate to themselves powers that committees and their chairpersons cherish.

Legislative Procedure

Because of their very different sizes, the House and Senate have fundamentally different procedures. In both, however, the rules of procedure have a profound impact on the legislative product. The House of Representatives, with its large size, cannot tolerate as much individual expression of its members as the Senate can, and its procedure is designed to ensure that the majority prevails. Consequently, the minority party and individual members often feel that they have been crushed by a legislative steamroller. The smaller Senate can more readily accommodate the peculiarities of its members and accordingly it allows far more freedom for debate and amendment.

Legislation in principle follows a regular path – a bill is introduced in the House or Senate, it is referred to a committee, voted on by the committee, and then sent to the full chamber for amendment and adoption. Then the bill is taken up the other chamber where it follows a similar course. The bills from the two chambers are seldom identical, so a conference committee is convened to iron out the differences. A compromise version of the bill is then adopted by both House and Senate and then sent to the president for his signature.

In practice, major legislation in today's Congress seldom follows this idealized path. Bills skip committee occasionally, they may be adopted as amendments to minor bills, bills may be packaged together as omnibuses to speed them through Congress, and so on. The variations on the standard legislative process are endless (Sinclair, 2011).

House Procedure

After important bills are reported favorably from committee, they normally go to the Rules Committee. The Rules Committee drafts a resolution, called a 'special rule,' that, on adoption by the House, determines the conditions under which the bill will be debated, amended, and voted upon. The power and flexibility of special rules to alter, amend, and waive the rules of the House is staggering. Special rules can either make no amendments in order (a closed rule), or place no restrictions on amendments (an open rule). Alternatively, they can make a specified list of amendments in order, they can declare amendments adopted without a vote, or they can amend amendments without the permission of the amendment's author. Special rules can alter or waive the rules of the House for the purposes of considering a particular bill. In short, special rules are infinitely flexible, limited only by the creativity of the Rules Committee, allowing the majority to do nearly anything it wants. Rules written by the Rules Committee must be adopted by a majority vote of the House. In general, the majority party members work closely with their party leaders to ensure that the position preferred by the party is able to prevail, and that potentially troublesome amendments are either forbidden, or considered in such a way that they will do the least possible harm to majority party control.

Senate Procedure

While action in the House is structured closely by its extensive rules, the Senate, by contrast, has relatively few rules and frequently ignores what rules it has. The Senate gives individual senators an almost unbelievably large amount of discretion and power. This has the predictable consequence of sometimes of paralyzing the Senate. The House works by assembling majorities and voting, but the Senate must work by a process of accommodating the individual senators, not by forming majorities, but by working to overcome the objections of individual senators.

The central feature of Senate procedure, around which all else is organized, is the possibility of the filibuster. Filibusters are efforts to defeat bills, not by voting them down, but by means of delay. The goal of filibusterers is to convince supporters of legislation that it will take so much time to pass the bill that they would be better off dropping it and moving on to something else.

Filibusters are possible because of three glaring omissions from Senate rules. The Senate lacks any means of limiting debating time, it lacks a 'germaneness' rule for interventions

and amendments, and it lacks a previous question motion. Because the House rules have all of these key features, dilatory tactics are not possible there. The usual filibustering tactics include the so-called 'extended debate,' whereby senators talk endlessly, and not necessarily about the bill in question, offering numerous amendments, which need not be germane to the bill, and offering numerous motions, such as suggesting the absence of a quorum, intended only to delay action. Filibusters can be ended by means of the 'cloture' process. If 60 senators are willing to vote for cloture, debate can be ended, but only after all amendments have been disposed of, and all senators have had an additional opportunity to speak for an hour.

Because even a single determined senator can cause a lengthy delay, losing the Senate the opportunity to consider other important legislation, the focus of Senate activity is not on breaking filibusters through cloture, but rather on avoiding them altogether. In advance of bringing legislation to the floor, bill sponsors often engage in extensive discussions with their colleagues in an effort to anticipate and satisfy objections. Most legislation passes the Senate with only minimal objection, in part because of efforts to build consensus early.

There have been no major changes to the rules governing filibusters since 1975, but in recent congresses there have been new efforts to make it easier for the majority to rule. Since the 1990s, the filibuster has become largely a tool used by the minority party to obstruct the agenda of the majority. Presidential nominations to positions in the executive and judicial branches have come to be routinely filibustered, resulting in significant delays and prolonged vacancies in important positions. To pass, bills must now effectively win a 60 vote supermajority. The Senate majority party, frustrated by delay and obstruction, has increasingly threatened to change the rules to make filibusters easier to curb. According to a traditional understanding of Senate procedure, rule changes, including changes to rules governing filibusters, are themselves subject to a filibuster. When they have been in the majority, both Democrats and Republicans have threatened to employ a novel procedure and change filibuster rules by a simple majority vote. To prevent this from happening, the minority party has made concessions and, at least temporarily, moderated their filibustering to keep the majority from changing the rules. It seems improbable, however, that the filibuster can survive much longer, when it serves primarily the interests of the minority party.

Congress and the President

By dividing the legislative and executive powers into separate branches, the authors of the US Constitution sought to encourage friction and disagreement in government. This plan has worked well for over two centuries, as Congress remains determinedly independent. Through the power of the veto, every president gains significant power in the legislative process. Vetoes of bills can be overridden by a two-thirds vote of both chambers of Congress, but in practice this happens seldom. In the past four presidencies, from 1989 to the present, there have been 95 total vetoes but only seven overrides. Presidents constantly use the threat of a veto to force Congress to make changes in pending legislation. The veto is potent, but it is mostly negative: presidents cannot readily use the veto power to force Congress to pass legislation.

Congressional independence is nowhere better demonstrated than in its handling of the federal budget. By statute, the president is required to submit to Congress each year a detailed budget proposal. Nothing, however, requires Congress to pay much attention to presidential proposals. Commonly in recent years the president's budget has been declared 'dead on arrival' at Capitol Hill, and Congress has gone on to draft its own, different budget, relying on its budget process, its committees, and its own budget agency. The president has influence over members of Congress, especially those from the president's own party; however, even members of the president's party are influenced strongly by their constituencies.

Congress and Foreign Policy

Congress defers to the executive branch to a great extent in foreign policy, but with important exceptions. Even though the Constitution gives Congress the power to declare war, power over warmaking drifted away from Congress to the president over the twentieth century, in part because of a need for speed and secrecy, and in part because of an unwillingness in Congress to challenge the president over the war power. Congress passed resolutions authorizing major conflicts in Iraq and Kuwait, but many other conflicts were initiated by the president without any authorization from Congress. The Korean War is the most prominent of these undeclared wars, but many other less bloody conflicts were begun entirely on the unilateral authority of the president, including invasions of Panama, Grenada, peacekeeping operations in Somalia and the Balkans, and support for insurgencies such as Libya in 2011.

In a series of decisions the federal courts made it clear that they were uninterested in adjudicating war powers disputes between Congress and the president (Fisher, 2000).

Congress passed the War Powers Resolution in 1973 over President Nixon's veto. It was an effort to delineate congressional and presidential powers over war. It ceded the president the power to introduce U.S. forces into situations involving hostilities for a period up to 90 days without congressional authorization. Forty years later, it appears that the War Powers Resolution has done practically nothing to restrain presidents. The development of drone warfare seems likely to shift the balance of power over warmaking even more in the president's direction. Since drones do not put U.S. forces in danger, they skirt the restrictions of the War Powers Resolution.

Polarization

To say that Congress is more polarized means that the ideological centers of the two parties have moved apart. For most of the twentieth century there was a substantial overlap between the two major parties. The most conservative Democrats were more conservative than many Republicans and the most liberal Republicans were more liberal than many Democrats. The overlap has vanished.

Polarization can be assessed by means of different kinds of scores that aggregate roll call voting of individual members into

an index of their overall voting tendency. The most common such measures in use today are the NOMINATE scores developed by Poole, Rosenthal, and McCarty. The mean NOMINATE scores of Republicans and Democrats in both the Senate and House have moved steadily away from the center since the 1970s. As of 2012, the parties were more polarized than at any in more than a century, possibly more polarized than at any other time in American history (McCarty et al., 2008).

The fact of increased polarization is undisputed, but the causes are complicated. As with any profound social change, it is wise to look beyond any single cause. At least three major explanations of polarization have been advanced. One is that the American electorate is more polarized and they not surprisingly elect more extreme representatives and senators (Abramowitz). A second is that Democrats and Republicans have 'sorted' themselves more efficiently into the correct party. Thee are currently far fewer Democrats being elected from conservative districts and fewer Republicans being elected from liberal districts (Fiorina et al., 2010). A third is that increased gerrymandering has made districts safe for one party or the other, which encourages members to move from the center. If representatives and senators are more or less assured of victory in the general election, losing a primary election becomes a greater risk to their reelection, and representatives will rationally shift from the center to appeal more to the sharp partisans who tend to dominate primaries. There is strong evidence to support the first two of these explanations, but the gerrymandering explanation is disputed by McCarty et al. (2009), who find that gerrymandering contributes only modestly to increased polarization. Further, gerrymandering cannot explain increased polarization in the Senate.

A polarized Congress functions differently than a non-polarized Congress. With the parties farther apart ideologically, it is harder to forge cross-party coalitions to pass legislation. In previous decades, a typical strategy in passing legislation was to assemble a coalition of most of one party, joined by members of the other party who were ideologically in agreement. In a polarized Congress major legislation tends to pass with few votes from the opposition party.

Sharp disagreements across the parties have led to the rise of highly confrontational tactics. Under Speaker Newt Gingrich, the Republicans in 1995 refused to pass appropriations bills, shutting down portions of the federal government, as a means of forcing President Bill Clinton to sign legislation cutting the budget deficit. In 2011, Republicans in the House of Representatives employed a similar tactic, refusing for months to pass legislation raising the federal debt ceiling, seeking to force President Obama to accept their budget plan (Draper, 2012). These theatrics create an uncertainty about whether the government will be able to function or pay its bills that was mostly absent in the era prior to polarization.

Democratic Accountability

Ideally, individual members of Congress should be held accountable for the collective actions of Congress, but this does not necessarily occur (Arnold, 1990). While members of Congress sometimes campaign for reelection by proclaiming the major legislative accomplishments of Congress, often they detach themselves from the institution as a whole and seek reelection for particular services rendered to the district or state. Adopting pork barrel projects such as dams, roads, and parks can help to make individual members popular, but the appearance of waste and venality can make Congress less popular. Fenno argued that representatives and senators distance themselves from Congress as an institution and seek to promote themselves separately, often at the expense of Congress as a whole (Fenno, 1978). The accountability of Congress to voters is inherently difficult because Congress acts as an institution, but its members are judged individually.

Connectionist Models of Concept Learning

Koen Lamberts, University of Warwick, Coventry, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A category is a collection of objects or events, and a concept is the mental representation of a category. Connectionist models assume that concept learning involves the development of associative links between mental representations of objects or events and mental representations of categories. These links form the basis of categorization, which is the process of generating the category name that corresponds to a given object. In this article, the basic principles of connectionist models of concept learning are presented, and their empirical and theoretical merits are discussed. The discussion starts with a simple model of concept learning (the delta rule model), which has formed the basis of much research on connectionist models of concept learning. Next, the fundamental problems of the delta rule model are highlighted. Finally, an alternative to the delta rule model is presented.

A category is a collection of objects or events. Concepts can be seen as mental representations of categories, and concept learning can be defined as learning to assign objects or events to categories. The study of concept learning has a long history in psychology. Experimental research on concept learning has revealed several regularities, which seem to apply across a wide range of stimuli and learning conditions. These regularities must be explained by any valid model of concept learning. A detailed overview of basic findings on concept learning is provided in *Concept Learning and Representation: Models*. For some time, connectionist models of concept learning have been popular (e.g., Ashby et al., 1998; Gluck and Bower, 1988a, 1988b; Kruschke, 1992). In connectionist models, it is assumed that concept learning involves the development of associative links between objects and categories. These links form the basis of categorization, which is the process of assigning an object to a category. In this article, the basic principles of connectionist models of concept learning are presented, and their empirical and theoretical merits are discussed. There are so many different connectionist models of concept learning that it is impossible to cover them all here. Instead, the article will focus on a few models that are well established and have been particularly influential. The discussion starts with a simple model of concept learning (the delta rule model) that has formed the basis of much research on connectionist models of concept learning. Next, the fundamental limitations of the delta rule model are highlighted. Finally, an alternative to the delta rule model is presented.

The Delta Rule Model

One of the simplest and best understood learning rules in connectionist models is the so-called delta rule, which was proposed by Widrow and Hoff (1960) and is formally equivalent to the learning rule in Rescorla and Wagner's (1972) model of associative learning (see Sutton and Barto, 1981). The delta rule is an error-correcting rule. It assumes that feedback is available on the classification performance of a network, and that this feedback is available for each stimulus that must be classified. A learning scheme that fulfills this condition is called a supervised learning scheme.

To illustrate the delta rule, assume that we have the simple model of concept learning shown in Figure 1. The model takes the form of a connectionist network, with two connected layers of processing units. The input layer is used to represent or encode the stimuli that can be presented, whereas the output layer represents the response alternatives (in a categorization context, each response alternative typically corresponds to a single category). Input coding is achieved by a number of units, each of which corresponds to a single feature or dimension of the stimulus. Furthermore, each input unit is connected to each output unit. The connections in the network have associated strength values. The strength of a connection determines the effect that activation of its source or input unit has on its output unit. In a network of this form, category learning is assumed to involve the modification of the strengths of the connections between input and output units in such a way that presentation of a stimulus to the input units will give rise to the activation of the output unit that corresponds to the category to which the stimulus belongs.

The input to the network on a given trial is represented by the pattern of activation across the input units. Suppose that each input unit represents a stimulus feature that can be either present or absent (such as 'red,' or 'large'). The set of features that characterizes a stimulus can then be represented by setting

Figure 1 Delta rule network architecture.

the activation of each input unit that corresponds to a feature that is present to 1, whereas the activation of the other units can be set to 0. Of course, other representation schemes are possible, depending on the nature of the stimuli and the requirements of the learning task.

Upon presentation of a stimulus, the activation of the output units is computed as follows:

$$a_o = \sum_i w_{io} a_i \quad [1]$$

in which a_o is the activation of output unit o, a_i is the activation of input unit i, and w_{io} is the strength of the connection between input unit i and output unit o. Next, feedback about the network's output activation pattern is provided, and the discrepancy between the current output pattern and the desired output pattern is computed. In a concept-learning task, the desired output would typically be that one output unit (corresponding to the correct category) is activated, whereas the other units remain inactive. For each output unit, an error value e_o is computed:

$$e_o = d_o - a_o \quad [2]$$

in which d_o is the desired output value for unit o. Finally, the connection strengths in the network are modified as follows:

$$\delta w_{io} = \lambda a_i e_o \quad [3]$$

in which δw_{io} is the change in the connection strength and λ is a learning rate parameter.

After a number of presentations of the entire set of stimuli in a category-learning task, the delta rule is guaranteed to produce a set of connection strengths that is optimal for the category-learning task at hand, within the constraints imposed by the architecture of the network (Kohonen, 1977). For some category structures, the simple network in Figure 1 is sufficient to achieve perfect categorization of all stimuli. If perfect categorization is impossible (for reasons that will be explained in this article), the delta rule still converges upon a set of connection strengths that produces the best performance that can be achieved with the network to which it is applied.

Evaluation of the Delta Rule Model

Delta rule networks have been evaluated in a large number of empirical studies on concept learning (e.g., Estes et al., 1989; Friedman et al., 1995; Gluck and Bower, 1988a,b; Shanks, 1990, 1991) with considerable success. However, although the delta rule model can explain important aspects of human concept learning, it has a major weakness: It fails to account for people's ability to learn categories that are not linearly separable. In a network of the kind described here, the activation of any output unit is always a weighted sum of the activation of the input units. This implies that the network can learn only categories that can be separated by a linear function of the input values. In human concept learning, linear separability does not appear to be an important constraint. It has been shown repeatedly that people can learn nonlinearly separable category structures without difficulty (e.g., Medin and Schwanenflugel, 1981; Nosofsky, 1987).

There are several ways in which delta rule networks can be modified to handle nonlinearly separable categories. One way is to augment the input layer of the network with units that become active only when particular combinations of two or more features are present in the input (e.g., Gluck and Bower, 1988b; Gluck, 1991). If enough configural units are present (and if they encode the correct combinations of features), such networks can be made to learn any category structure using the delta rule. However, it is not clear that learning in such networks corresponds well to human learning, or that configural cue networks explain categorization after learning (Choi et al., 1993; Macho, 1997; Nosofsky et al., 1994; Palmeri, 1999). Moreover, the number of possible configural units grows exponentially with the number of stimulus dimensions. Configural cue models are therefore not particularly attractive as models of human concept learning.

A second way of modifying delta rule networks so that they can learn nonlinearly separable categories involves the use of a layer of 'hidden' units between the input and output units. Rumelhart et al. (1986) proposed a generalization of the delta rule for such networks. This backpropagation-of-error rule is used to determine how much the connection strengths between input and hidden units, and between hidden and output units, should be changed on a given learning trial to achieve the desired mapping between input and output. If the units in such multilayer networks have nonlinear activation functions, backpropagation networks can learn nonlinearly separable categories; in fact, they can learn arbitrary mappings between inputs and outputs, provided that they contain a sufficient number of hidden units (Hornik et al., 1989).

Despite their intuitive appeal and obvious computational power, backpropagation networks are not adequate as models of human concept learning (e.g., Kruschke, 1993). Their most important shortcoming is that they suffer from 'catastrophic forgetting' of previously learned concepts when new concepts are learned (McCloskey and Cohen, 1989). To overcome this difficulty, various alternative learning schemes have been proposed. One of the most successful alternatives was developed by Kruschke (1992), who proposed a hidden-unit network that retains some of the characteristics of backpropagation networks but does not inherit their problems.

Multilayer Networks

ALCOVE (Kruschke, 1992, 1993) is a connectionist network with three layers of units: an input layer, a hidden layer, and an output layer (see Figure 2). The model is based on an exemplar theory of concept learning and categorization, Nosofsky's (1986) Generalized Context Model (GCM; *see* Concept Learning and Representation: Models). Each input unit i of ALCOVE encodes a single stimulus dimension and is gated by a dimensional attention weight α_i, which reflects the relevance of the dimension for the learning task at hand.

Each hidden unit has a 'position value' on each stimulus dimension, which means that each hidden unit corresponds to a particular stimulus or exemplar. Whenever an input pattern is presented to the network, each hidden node is activated according to the similarity between the stimulus it represents

Figure 2 Architecture of the ALCOVE model of concept learning.

and the input pattern. In ALCOVE, similarity is defined as in Nosofsky's GCM:

$$a_j^{hid} = \exp\left[-c\left(\sum_i \alpha_i \left|h_{ij} - a_i^{in}\right|^r\right)^{q/r}\right] \quad [4]$$

in which a_j^{hid} is the activation of hidden unit j, h_{ji} is the position of hidden unit j on stimulus dimension i, c is a positive constant called the specificity of the hidden unit, a_i^{in} is the activation of input unit i, and r and q determine the similarity metric and similarity gradient, respectively.

Each hidden unit is connected to output units that correspond to response categories. The category units are activated according to the following rule:

$$a_k^{out} = \sum_j w_{kj} a_j^{hid} \quad [5]$$

in which w_{kj} is the association weight between hidden unit j and category unit k. This is the same activation rule used in the simple delta rule network discussed in this article (see eqn [1]). Finally, category unit activations are translated into response probabilities by the following rule:

$$P(K) = \exp(\phi a_j^{out}) / \sum_m \exp(\phi a_m^{out}) \quad [6]$$

where ϕ is a scaling constant. ALCOVE employs a variation of the backpropagation learning rule to adjust dimensional attention weights α_i and association weights w_{kj} in the course of learning (for details of the learning rule, see Kruschke, 1992). As a result of these adjustments, the network will eventually learn to classify each stimulus into the correct category.

ALCOVE has great advantages over the simple delta rule network for concept learning. The model is not affected by the linear separability constraint. Like standard backpropagation networks, ALCOVE can learn arbitrary mappings between stimuli and categories. Moreover, ALCOVE does not suffer from catastrophic forgetting (Kruschke, 1993). Most important, however, is the correspondence between ALCOVE's predictions about concept learning and human performance (e.g., Choi et al., 1993; Kruschke, 1992, 1993; Nosofsky et al., 1992; Palmeri, 1999). Since its original formulation, the model has undergone a number of refinements and modifications, which allow it to explain concept learning in a variety of conditions (e.g., Kruschke, 1996, 2008; Kruschke and Johansen, 1999; Denton and Kruschke, 2006). The model has also provided inspiration for some of the principles of other successful connectionist models of concept learning (e.g., Love et al., 2004). ALCOVE and its successors ultimately derive their strength from a combination of the principles of exemplar-based processing with those of associative learning.

Conclusions and Future Directions

Whereas connectionist models such as ALCOVE can explain many important aspects of human concept learning, it is becoming increasingly clear that they also have fundamental limitations. The models that were reviewed here all assume that concept learning is an associative process, in which links between stimulus and category representations are modified. There is little doubt that many concepts are learned in this way. However, the associative model does not apply to the learning of all concepts. Some concepts are learned by a process of rule discovery, which has characteristics that are very different from those of connectionist models of learning. An important challenge is to determine when associative models and rule-based models of concept learning apply. There have been a number of proposals for how associative and rule-based concept-learning principles can be combined (e.g., Ashby et al., 1998, 2010; Erickson and Kruschke, 1998; Love and Tomlinson, 2010), and it is likely that such models will become increasingly prominent.

Abstract

The personality trait of conscientiousness is related to a great number of important life outcomes. To better understand why the influence of conscientiousness is so pervasive, the current article provides a broad overview of the trait. First, the lower-order facet structure of conscientiousness is described, including a description of some of the most common ways to measure both the broad trait as well as the facets. Next, we review the influence of conscientiousness on several life domains and discuss pathways that relate the two. Finally, the development of conscientiousness is explored.

Conscientiousness is a personality trait that is best known for belonging to the taxonomy of the 'Big Five' personality traits (Goldberg, 1993), which also includes extraversion, agreeableness, neuroticism, and openness. Individuals high in conscientiousness tend to follow socially prescribed norms for impulse control, to be goal directed, planful, and to be able to delay gratification (Roberts et al., 2004). While typically thought of as belonging to the Big Five, constructs related to conscientiousness were discussed as far back as Aristotle and are included in classic personality taxonomies set forth by Cattell (1957), Eysenck (1947), Gough (1956), Tellegen and Waller (2008).

As seen in the definition, conscientiousness is not a singular dimension but instead encompasses a broad range of lower-order individual differences. In this review, we first unpack these lower-order facets of conscientiousness, and describe commonly used measures that assess conscientiousness and its lower-order facets. Much of the recent interest in conscientiousness stems from its associations with a number of important life outcomes. Thus, in the following section, we discuss the relationship between conscientiousness and important life outcomes, detailing how lower-order facets can help explain these associations. Finally, we describe the development of conscientiousness over the life span, focusing on the lower-order components.

The Lower-Order Structure of Conscientiousness

Personality traits describe the relatively enduring patterns of thoughts, feelings, and behaviors of individuals. While typically thought of as decontextualized constructs, traits can range from broad, overarching concepts to more specific, concrete manifestations. In other words, personality traits can be conceptualized as existing within a hierarchical structure, with broad constructs structured above more specific, lower-order facets of these traits, and behavioral, cognitive, and affective manifestations of these traits falling at even lower ends of the hierarchy (Jackson et al., 2009; Markon et al., 2005; Roberts et al., 2004). At the highest levels of the hierarchy, personality traits can be meaningfully organized into two (Digman, 1997), three (Tellegen and Waller, 2008), and even four factors (Markon et al., 2005), before settling into the well-known Big Five factors (Goldberg, 1993).

Similar to the hierarchical structure of personality traits, the trait of conscientiousness can be decomposed into narrower, lower-order facets, which can be broken down even further into more concrete behaviors, thoughts, feelings, and habits, like setting goals for oneself or turning work in on time. At the most basic two-factor division, conscientiousness can be thought of as consisting of two components, a proactive component and an inhibitory component (Costa et al., 1991; Jackson et al., 2010; Roberts et al., 2005a). The proactive component refers to being goal oriented and striving to do well in one's endeavors, while the inhibitory component refers to being responsible, delaying gratification, and controlling impulses. Together, these two overarching components provide a structure under which the rest of the facets can be organized. It should be noted that an alternative perspective finds that the two-facet structure of conscientiousness consisting industriousness and orderliness (DeYoung et al., 2007). While this two-factor solution may initially seem similar to the proactive and inhibitory components of conscientiousness, empirical examinations of the lower-order structure of conscientiousness show that industriousness and orderliness fall in the proactive component only (Roberts et al., 2005a).

More clearly defined facets emerge as one moves down the conscientiousness hierarchy. Three-factor solutions typically consist of factors associated with achievement, self-control, and responsibility (Jackson et al., 2010; Roberts et al., 2005a), though few studies have explicitly tested three-factor solutions. Perhaps the most agreed upon level of analysis for conscientiousness is the four-factor solution. Numerous studies identify four interpretable factors, namely orderliness, industriousness, responsibility, and self-control (Jackson et al., 2010; Peabody and De Raad, 2002; Roberts et al., 2004). While these four facets replicate across most studies, additional facets of conscientiousness, such as conventionality and formality, appear further down the hierarchy (Roberts et al., 2004, 2005a). Currently, however, these additional facets do not replicate across studies as consistently as the four-factor solution, making it difficult to identify the structure of five-factor solutions or greater.

Two facets of the four-factor solution, orderliness and industriousness, fall under the proactive domain of conscientiousness. Individuals high in orderliness are likely to be neat and clean, and situate their belongings in an organized

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25047-2

fashion (Jackson et al., 2009). To a lesser extent, orderliness also includes one's proclivity toward making and adhering to plans and utilizing to-do lists and planners that aide in a more organized and orderly day. Industriousness refers to how hard-working one is, as well as one's ability to persevere and strive for success. Industrious individuals like to finish what they start, and will work long hours or even take on extra work in order to do a thorough job (Jackson et al., 2009, Mike et al., 2014). Individuals low in industriousness may avoid work, procrastinate, or give up easily when facing adversities. Naturally, high levels of industriousness are associated with succeeding in achievement domains such as academics and work.

Self-control falls on the inhibitory side of conscientiousness. Self-control may be labeled differently from measure to measure and is commonly called impulse control, impulsivity (reversed), constraint, or self-discipline. Within other fields, it may even be referred to as effortful control or executive functioning (DeYoung, 2011). Regardless of the name, self-control refers to the ability to inhibit impulses and avoid being reckless or out of control. Individuals high on self-control are able to put off immediate gratification in order to attain larger goals. Individuals low on self-control are more likely to make impulsive purchases, to put off or cancel plans at the last minute, and to be unable to control reactions when feeling angry or frustrated (Jackson et al., 2010). As indicated in the dissent in naming this construct, many disagree as to which Big Five trait self-control is associated with. Sometimes self-control is considered to be a facet of extraversion because of its relationship with sensation seeking; self-control can also be thought of as a component of neuroticism, where impulsive actions are likely to occur because of emotional instability (DeYoung, 2011). However, continuing evidence indicates that self-control is primarily related to conscientiousness (Paunonen, 1998; Roberts et al., 2004).

The final facet of the four-factor solution, responsibility, can be considered as both inhibitory and proactive. Sometimes referred to as reliability, this facet describes one's tendency to uphold obligations and follow rules. Those high in responsibility are less likely to break promises, miss appointments, or oversleep (Jackson et al., 2010). Those low on responsibility may be described as unreliable or flighty and are more likely to bend or break rules. The facet of responsibility often tends to be strongly associated with the trait of agreeableness, partly because the behaviors associated with the facet frequently involve an interpersonal context.

Conceivably, conscientiousness consists of more than four factors, and, indeed, solutions up to eight factors have been found (Roberts et al., 2004). Three additional facets are of particular note, as they have independently emerged across a number of different studies: conventionality, formality, and punctuality (MacCann et al., 2009; Roberts et al., 2004, 2005a). Conventionality is the inclination to support and follow the norms of society in order to maintain good social environments. Individuals high in conventionality are more likely to uphold family and cultural traditions, while individuals low in conventionality may be described as nonconforming or untraditional. Conventionality also extends to having more traditional or conservative beliefs, particularly within the political and spiritual spectrum, and is closely related to the trait of openness to experience (Johnson, 1994). Those high in formality can best be described as having a sense of propriety, which includes being polite and proper, and keeping one's physical appearance neat and clean. They may call others by formal titles, say please and thank you, and are less likely to swear. It should be noted that despite the different definitions for conventionality and formalness, in practice it is often difficult to meaningfully differentiate between the two as they are highly related (Jackson et al., 2010).

Finally, punctuality describes the practice of doing things in a timely manner and could be considered the narrowest facet of conscientiousness. Interestingly, however, punctuality tends to be equally related to each of the other facets of conscientiousness – unlike the other facets of conscientiousness – and thus could serve as a useful marker for overall levels of conscientiousness (Jackson et al., 2010).

In summary, conscientiousness consists of many distinct lower-order facets. Much like higher order personality traits, facets of conscientiousness can be ordered in a hierarchy. While the overarching concept of conscientiousness is generally agreed upon, a standard facet-level structure has not reached consensus. The most commonly identified facets are orderliness, industriousness, self-control, and responsibility (Roberts et al., 2012). However, five-factor solutions, which typically include conventionality or decisiveness, have been suggested (Jackson et al., 2009; Saucier and Ostendorf; Peabody and De Raad, 2002). Further down the hierarchy, there are 6-, 8-, and even 9-component solutions that may represent reasonable factor structures (MacCann et al., 2009; Madhavan, 2004; Roberts et al., 2004, 2005), though there has been less research to replicate these findings. As such, the measurement of conscientiousness reflects the discrepancy in facet solutions, as facets names and number of facets vary from scale to scale.

How to Measure Conscientiousness

Numerous measures of conscientiousness exist. Many of these measures belong to larger omnibus inventories that assess all of the Big Five factors, though some come from measures outside of the Big Five. The choice of which measure to use depends upon the researcher's needs and time constraints. Some measures aim to assess only the broad construct of conscientiousness while others break the assessment up into specific facets. Adding to the confusion, many of these facet measures have names that are specific to the scale, making comparisons across measures difficult. Measures also vary in length, ranging from two items to dozens of items.

One of the most common measures of conscientiousness is from the NEO-PI-R (Costa and McCrae, 1992). Though it was originally designed to measure only neuroticism, extraversion, and openness (hence NEO), it was later revised to include agreeableness and conscientiousness. The 48-item NEO measure of conscientiousness includes six facets, which are labeled: competence (closely related to the facet of industriousness), order, dutifulness (responsibility), achievement striving (industriousness), self-discipline (self-control), and deliberation (self-control). A related measure is the NEO-FFI, which is an abridged version of the NEO-PI-R, including only 12

items for conscientiousness. The NEO-FFI was not designed to assess particular facets but was intended to briefly measure the Big Five under time constraints. However, further research has indicated that the NEO-FFI can be used to assess a limited number of broader facets (Chapman, 2007; Saucier, 1998). For conscientiousness, this includes orderliness, goal-striving (industriousness), and dependability (responsibility).

Another common measure of conscientiousness is the Abridged Big Five Circumplex (AB5C; Hofstee et al., 1992). The AB5C has 486 items and includes nine facets of conscientiousness: organization, purposefulness, efficiency, rationality, dutifulness, orderliness, conscientiousness, perfectionism, and cautiousness. Unfortunately, these facets do not adequately cover the facets of conscientiousness discussed above, and appear to reduce to a three-factor solution (Roberts et al., 2005a). The purposefulness, efficiency, and rationality scales tap industriousness, while the perfectionism scale is mostly associated with orderliness; cautiousness being the only scale that reflects the self-control facet (Roberts et al., 2005a). Part of the reason for this lack of coverage is the way the AB5C derived its facets. The AB5C creates facets by crossing one Big Five trait with another under the idea that items do not neatly describe a single trait but instead are blends of multiple traits (e.g., being responsible may represent high levels of conscientiousness and agreeableness). Unfortunately, it appears that not all combinations of traits had an adequate number of items to meaningfully differentiate between these nine facets, resulting in a reduced number of facets captured.

The Big Five Inventory (BFI; John et al., 1991) is commonly used to measure the Big Five traits and includes nine items on conscientiousness. The BFI is a shorter length omnibus inventory and thus was not initially developed to measure facets of conscientiousness. However, two facets of conscientiousness may be captured using the BFI: self-discipline (self-control) and order (Soto and John, 2009).

The Ten Item Personality Inventory (TIPI, Gosling et al., 2003) was developed to be a very short and efficient measure of conscientiousness. Consisting of just two conscientiousness items, individuals rate how much they agree with the statements, "I see myself as dependable, self-disciplined," and "I see myself as disorganized, careless" (reverse-scored). Though longer measures are generally preferable (Credé et al., 2012), short measures such as the TIPI do provide adequate assessment of conscientiousness if one is under extreme time constraints.

The Multidimensional Personality Questionnaire (Tellegen and Waller, 2008) departs from the previous measures in that it does not explicitly measure the Big Five but instead focuses on the Big Three (positive emotionality, negative emotionality, and constraint). Here, conscientiousness is captured by constraint, which encompasses the lower-order facets of self-control, traditionalism (conventionality), and harm avoidance (which is more closely related to neuroticism and agreeableness). Another divergence from previous measures is that the 77-item constraint measure uses true–false items rather than likert scales.

The Hogan Personality Inventory (Hogan, 1992) has 206 items used to measure six personality trait dimensions called intellectance, adjustment, prudence, ambition, sociability, and likeability. Here, conscientiousness is referred to as prudence and is intended to identify individuals who are conscientious, conforming, and dependable. Facets of prudence are moralistic (conventional), mastery (industriousness), virtuous (formality), not autonomous (industriousness), not spontaneous (self-control), impulse control (self-control), and avoids trouble (responsibility).

A relatively new measure of conscientiousness is the Chernyshenko Conscientiousness Scales (Hill and Roberts, 2011). Six different facets are assessed across 60 items (orderliness, self-control, responsibility, traditionalism (conventionality), industriousness, and virtue). The virtuous facet is unique in that it assesses the tendency for conscientiousness individuals to be responsible members of the community who are honorable and rule abiding. It shares some overlap with the responsibility facet but is broader in scope and concerns issues of right and wrong rather than the tendency to follow through with personal obligations.

Conscientiousness can also be assessed using adjectives rather than statements (Saucier and Goldberg, 1996). The Conscientiousness Adjective Checklist (Jackson et al., 2009; Roberts et al., 2004) was designed to do exactly that. It consists of 123 personality adjectives that measure the facets of conscientiousness. This includes orderliness, industriousness, impulse control, responsibility, conventionality, and decisiveness (Roberts et al., 2004). Examples of adjectives included in the scale are organized, precise, thorough, responsible, reliable, and cautious.

Typical measures of personality traits such as the ones described above collapse items that tap thoughts, feelings, and behaviors to create an overall composite trait score. However, a scale was created in order to solely target the behavioral manifestations of conscientiousness, eschewing the assessment of thoughts and feelings (Jackson et al., 2010). Assessing only behaviors results in a more precise measure of an important component of conscientiousness, as such a scale will assess simply whether or not people behave conscientiously – regardless of their thoughts or feelings. The Behavioral Indicators of Conscientiousness scale (BIC; Jackson et al., 2010) includes a large pool of conscientiousness behaviors (185 behaviors ranging from cleaning a toilet, to canceling plans, to writing down important dates) that are rated on how often respondents engage in those behaviors. The BIC is ordered hierarchically and consists of a number of lower-order facets, depending on how broad or narrow the researcher's interest. Behavioral facets include: avoiding work, organization, impulsivity, antisocial behaviors, cleanliness, laziness, industrious, punctuality, formalness, responsibility, and appearance.

Other measures of conscientiousness that are less common, but just as valid, include the 20-item conscientiousness measure from the HEXACO inventory (Lee and Ashton, 2008). In this scale, conscientiousness is measured by assessing four facets: organization (orderliness), diligence (self-control), perfectionism (industriousness), and prudence (self-control). The Big Five Aspect Scale (BFAS; DeYoung et al., 2007) assesses two facets per Big Five trait (industriousness and orderliness for conscientiousness) using 10 items. Finally, the International Personality Item Pool (http://ipip.ori.org/) is a useful resource that offers a number of conscientiousness measures in addition to the AB5C and BFAS.

Conscientiousness and Important Life Outcomes

Conscientiousness plays an integral role in many important life outcomes, spanning success in school to living a longer and healthier life. Often, the associations between conscientiousness and these life outcomes are at levels equal to, if not better than, gold-standard predictor variables such as intelligence or socioeconomic status (Roberts et al., 2007b). This section discusses the various outcomes linked to conscientiousness and considers pathways responsible for each of the associations.

Conscientiousness is one of the best predictors of academic achievement, predicting GPA above and beyond even intelligence (Noftle and Robins, 2007). Conscientious students tend to have better grades, especially those who are high on the facet of impulse control (MacCann et al., 2009; Noftle and Robins, 2007; Paunonen and Ashton, 2001). These positive associations between conscientiousness and academic achievement are thought to be the result of how conscientious students think about school, their abilities, and the effort they put into achieving their academic goals. Conscientious students are more motivated to succeed in academic settings (Richardson and Abraham, 2009) and believe in their ability to be successful (Caprara et al., 2011). They are also more likely to couple their interests and self-concept in the domains in which they are successful (Denissen et al., 2007). For example, a conscientious student who makes good grades in geography is likely to both feel like she is good at geography and also be interested in geography. This interest flows back into one's achievement behaviors, which ultimately leads to higher grades. In general, conscientious students also devote more time to studying, completing projects, and turning assignments in on time. Together these characteristics make it more likely that conscientious students persevere in school, even through difficult or stressful situations.

As individuals leave school and enter into the work force, conscientiousness is again an important key to success. Conscientious people tend to earn more money (Ng et al., 2005; Spurk and Abele, 2011), are more satisfied with their jobs (Bowling and Burns, 2010; Ng et al., 2005), and are more likely to receive promotions (Ng et al., 2005) compared to those low in conscientiousness. Just as academic success was driven by the fact that conscientious individuals were engaged in effective academic behaviors, they are also, in effect, good workers. Conscientious individuals have greater career achievement related goals (Spurk and Abele, 2011), better attitudes toward their work (Bowling and Burns, 2010; Ng et al., 2005), they show more commitment to their jobs, and work well independently as well as in groups (Spurk and Abele, 2011; Sutin and Costa, 2010). Moreover, conscientious individuals tend to avoid detrimental activities such as stealing, drinking on the job, being tardy or missing work, and they are less likely to leave their jobs (Bowling and Burns, 2010; Roberts et al., 2007a).

Conscientiousness is also related to health and physical well-being. People who are conscientious report having fewer health problems than people who are not conscientious (Friedman et al., 1993; Lodi-Smith et al., 2009; Roberts et al., 2009) and conscientious individuals tend to live longer than their nonconscientious counterparts (Friedman et al., 1993; Hill and Roberts, 2011; Roberts et al., 2007b). Those low in conscientiousness are also more likely to develop specific diseases. such as metabolic syndrome, Alzheimer's disease, lung disease, and heart disease, and are also more likely to have a stroke (Sutin et al., 2011; Terracciano et al., 2013; Weston et al., 2014).

Most likely, conscientiousness individuals have more positive health outcomes due to engaging in more healthful behaviors, such as exercising and eating well (Lodi-Smith et al., 2009). Similarly, they are more likely to avoid unhealthful behaviors (Hampson et al., 2000), such as smoking, using drugs, alcohol, or engaging in risky driving or sexual behaviors (Jackson et al., in press; Weston and Jackson, in press; Roberts and Bogg, 2004; Friedman et al., 1995). If health issues do arise, conscientious individuals are more likely to adhere to their medical regimens (Hill and Roberts, 2011). By following their doctors' advice, and taking prescribed medications as needed, they are better able to overcome health ailments and prevent health declines. The association between conscientiousness and health emerges early in life – childhood levels of conscientiousness and related facets predict longevity and markers of health decades later (Friedman et al., 1993; Moffitt et al., 2011).

Conscientiousness also plays a role in the success and maintenance of romantic relationships. Conscientious people are less likely to get divorced (Solomon and Jackson, 2014), with some studies demonstrating conscientiousness' effect across decades (Roberts and Bogg, 2004). Likely this is a result of people high in conscientiousness having higher levels of relationship satisfaction and commitment levels (Dyrenforth et al., 2010; Solomon and Jackson, 2014b). In addition, highly conscientious people do fewer things to jeopardize their relationships (Hill et al., 2013). For example, infidelity is one of the main reasons for divorce, and conscientious individuals are less likely to cheat on their spouses (Buss and Shackelford, 1997). They are also less likely to abuse their spouses (Buss, 1991). Similarly, conscientious people are more likely to engage in relationship maintenance behaviors, such as correcting interpersonal mistakes and engaging in constructive problem solving (Baker and McNulty, 2011). Finally, conscientious individuals are more forgiving (Hill and Allemand, 2012), likely resulting in fewer disagreements and fights among couples.

Finally, it is noteworthy that the effects of conscientiousness on various life domains can extend beyond the conscientious individual and into the lives of close others. For example, the spouses of conscientious individuals tend to have better health outcomes (Roberts et al., 2009c) and work outcomes (Solomon and Jackson, 2014a).

While being high in conscientiousness has great benefits for school, work, health, and relationships, being low in conscientiousness can have serious negative consequences. First, levels of conscientiousness can have financial repercussions. Those low in conscientiousness are poor at managing their finances. They are less likely to save money and often have low credit scores (Bernerth et al., 2012; Webley and Nyhus, 2006). People low in conscientiousness are also more prone to gamble, particularly if they are highly impulsive (Myrseth et al., 2009). Moreover, individuals low in conscientiousness are more likely to engage in criminal behaviors (Jones et al., 2011; Wiebe,

2004), and low levels of conscientiousness predict getting arrested more often (Clower and Bothwell, 2001). Once arrested, prisoners with low conscientiousness levels spend a longer time in prison (Ireland and Ireland, 2011). Overall, it appears that conscientious individuals have positive life outcomes though engaging more often in constructive behaviors and avoiding harmful and counterproductive behaviors.

Development of Conscientiousness over the Life Span

While personality traits are relatively stable, they also demonstrate a degree of malleability and retain the capacity to change across the life. This means that conscientiousness is not a static construct, but can change over time – with individuals either increasing or decreasing with age. There are multiple ways to conceptualize this change. First, change can be thought of in terms or rank order stability – that is, how a person ranks on a trait compared to others. The rank order stability of conscientiousness increases steadily with age until plateauing between the ages of 50 and 70 (Caspi et al., 2005; Roberts and DelVecchio, 2000). This means that an individual who is above average on conscientiousness as a child will likely be above average on conscientiousness as an older adult.

However, these traits also remain open to outside influences and can change and develop over time. Mean level changes, or how a trait changes in absolute terms, also occur across the life span. In general, mean level changes in personality traits occur in the direction of greater psychological maturity (Roberts et al., 2008). Unsurprisingly, conscientiousness is part of this general trend toward maturity, and typically individuals increase in conscientiousness throughout the life span. Across a number of cross sectional and longitudinal studies conscientiousness was found to increase from young adulthood up to the age of 60 (Roberts et al., 2003b; Soto and John, 2012). This normative pattern of development replicates across a number of different cultures and countries, including Germany, Italy, Portugal, Croatia, South Korea (McCrae et al., 1999). Out of all of the Big Five traits, conscientiousness is the trait that evidences the largest increases, with increases as large as one full standard deviation across the life span (Roberts et al., 2005b).

While conscientiousness tends to increase across the life span, the rate and direction of change differs depending on age. Young adulthood has been identified as an especially important period for personality development and is possibly the period when personality traits change the most (Roberts et al., 2006b). In late childhood and adolescence, conscientiousness may demonstrate a negative trend before beginning to increase in young adulthood and continue to increase throughout adulthood (Soto et al., 2011). In old age, there is some recent evidence that conscientiousness may again demonstrate declines (Wortman et al., 2012). In general, findings regarding the trajectory of change in old adulthood are less cohesive than those for young and middle adulthood, as not all studies find older adults lower in conscientiousness (Allemand et al., 2008; Jackson et al., 2009).

The longitudinal studies of development that identify declines in conscientiousness during old age may differ from the studies that do not find declines in older adulthood in part because of the measures used to assess conscientiousness. Although conscientiousness as a whole generally increases across the life span, the facets of conscientiousness may each have unique developmental trajectories, demonstrating different trends from one another as well as from conscientiousness overall. Several studies examining the specific patterns of the development of conscientiousness facets find evidence for differences in development across the facets. For example, self-control increases across young adulthood and old age (Jackson et al., 2009; Soto et al., 2011). Industriousness demonstrates a similar pattern, increasing across the life span, though some evidence suggests that most of the changes occur earlier in adulthood (Jackson et al., 2009; Soto and John, 2012; Terracciano et al., 2005). Evidence regarding the development of responsibility suggests steady increases throughout the life span (Jackson et al., 2009). Conventionality does not show differences from young adulthood to middle adulthood, but older adults were found to be significantly more conventional than middle-aged adults (Jackson et al., 2009). Finally, the facet of orderliness differs from previous facets, as orderliness undergoes virtually no changes across the life span (Jackson et al., 2009; Soto et al., 2011, Soto and John, 2012). Overall, increases in conscientiousness earlier in life can be thought of as mainly resulting from increases in impulse control and industriousness, while increases in later adulthood are driven by changes in impulse control, reliability, and conventionality.

While the majority of people increase in conscientiousness as they age, there is a significant amount of people who do not change at all on conscientiousness, or perhaps even decrease (Lüdtke et al., 2011). These variations in development are thought to occur because of the unique experiences people go through and the roles that they take on throughout life (Lodi-Smith, 2007). While it is still unclear what experiences drive changes in conscientiousness, a number of studies have begun to associate life experiences with changes in conscientiousness.

Some of the most influential experiences relate to achievement, particularly achievement within academic settings. Students tend to increase in conscientiousness during their final year of high school, likely in preparation for the new responsibilities they anticipate taking on in college or in the workforce (Bleidorn, 2012). However, individual experiences are important as not everyone follows this pattern. Those who are not invested in school tend to change less compared to those that do invest in school. Similarly, failing an exam is associated with decreases in conscientiousness compared to those that did not fail an exam (Lüdtke et al., 2011).

Leaving school and obtaining one's first job is also associated with increases in conscientiousness (Specht et al., 2011). Similar to the findings in school settings, individuals who invest in their work also tend to increase in conscientiousness (Roberts et al., 2003a; Roberts et al., 2006a). Again, the opposite is also true; people who de-invest in work, such as committing counterproductive work behaviors, tend to become less conscientious, contrasting the typical developmental trend (Hudson et al., 2012; Roberts et al., 2006a).

In addition to one's level of conscientiousness predicting health and health behaviors, changes in conscientiousness also relate to health and changes in health behaviors. In one study, increases in conscientiousness were positively related

with changes in preventative health behaviors, such as healthy eating, exercising, and safe driving (Takahashi et al., 2013). These findings suggest that changes in conscientiousness are associated with changes in the health process. Likely, as people increase in conscientiousness, they increase in the ability and tendency to take better care of themselves, ultimately resulting in better overall health (Takahashi et al., 2013). Changes in health behaviors can also help explain changes in conscientiousness. For example, low levels of conscientiousness are associated with substance abuse in middle age, and continued substance abuse in turn is associated with nonnormative decreases in conscientiousness (Roberts and Bogg, 2004).

There is evidence that romantic relationships can impact the development of conscientiousness. For one, simply entering into a first romantic relationship can lead to increases in conscientiousness (Neyer and Asendorpf, 2001; Neyer and Lehnart, 2007). Relationship length may also have important implications for development. Evidence suggests that the longer women stay married, the more conscientious they become (Roberts and Bogg, 2004). Such increases may be a function of how conscientious behaviors are rewarded in the context of the relationship. Finally, divorce can impact conscientiousness, though evidence suggests effects differ depending on one's gender. One study found that conscientiousness increased after a divorce (Specht et al., 2011), while another study, consisting solely of women, found conscientiousness decreased after a divorce (Roberts and Bogg, 2004). Though further research is needed to determine the nature of these findings, one possible explanation is that divorced women may have fewer responsibilities because they no longer have to take care of their husbands, resulting in lower levels of reported conscientiousness, whereas men's responsibilities may increase after a divorce.

Criminality and externalizing behaviors, two correlates of conscientiousness, exhibit patterns of change over time that seem to complement the way conscientiousness develops (Roberts et al., 2009a). Criminality and externalizing behaviors are at their highest at ages when people are lowest in conscientiousness, and they decrease as conscientiousness increases. It is unclear whether changes in criminality and externalizing behaviors are associated with changes in conscientiousness, though some emerging studies suggest this is the case. For example, the development of conscientiousness is related to the development of drinking and drug use behaviors such that decreases in alcohol usage are related to increases in conscientiousness and impulse control (Littlefield et al., 2010). Similarly, decreases in tobacco consumption are related to increases in the facet of responsibility (Roberts and Bogg, 2004).

Conclusion

Conscientiousness is a hierarchical structure that, at its broadest level, describes individual differences in the tendency to be industrious, organized, responsible, and self-controlled, while, at its lowest level, describes specific behaviors related to these traits, such as keeping appointments and cleaning regularly. There are numerous ways to assess conscientiousness, and it is possible to do so at nearly every level of the hierarchy – from measures that look at conscientiousness as a whole to those that only examine behaviors. It is hoped that future researchers will use narrower levels of analysis to better understand the relationship between conscientiousness and life outcomes as well as to better understand how conscientiousness may development over the life span.

Conscious Control during Childhood, Development of

Vladimir A Fomichov, National Research University Higher School of Economics, Moscow, Russia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reconstructs the panorama of studies on the development of conscious control during childhood that were carried out in the 1990s and 2000s. The principal attention is paid to the main stream in this direction: the achievements of the positive psychology movement (i.e., the branch of psychology aimed at supporting and developing the positive qualities of the person). With this aim, both broadly known and much less known but deep studies carried out in adjacent fields are analyzed.

The goal of studying the development of consciousness in childhood was posed as far back as in the end of the nineteenth century by J.M. Baldwin and in the first third of the twentieth century by L. Vygotsky. A large-scale research in this field was started only in the 1990s. However, by the beginning of the 2000s one was able to find in the scientific literature rather contradictory points of view concerning this problem.

The Birth of a New Paradigm in Psychology: The Enhancement of Positive Qualities

It seems that the best angle of look at the problem of development of conscious control (CC) during childhood can be found in the context of the main stream in modern psychology – the positive psychology movement. The reasons for this idea are as follows.

During the 1990s, it was possible to observe the steady growth of the number of children at school-age in the developed countries encountering various social, emotional, and behavioral problems. Numerous observations provide the possibility to conjecture that, to a large extent, it was a consequence of more intensive interaction with computers at lessons and at home and of the stormy Internet's expansion. Besides, the criminal films and horror films continued to negatively influence the mental state of very many children and adolescents, in particular, causing anxiety and aggression. These negative shifts became sufficiently noticeable by the beginning of the 2000s. According to the US Public Health Service (2000), approximately one-fifth of children and adolescents experienced problems showing their need for mental health services.

As a way out, many psychologists indicated the importance of promoting children's social and emotional experience in schools. As a consequence, a new paradigmatic shift was observed in psychology: a shift from the accent on repairing weakness to enhancing positive qualities and preventing the problems before they arise (Seligman and Csikszentimihalyi, 2000). As a result, the positive psychology movement appeared; the principal objective of this movement is studying the positive features of human development, in particular investigating such significant traits of the person as "subjective well-being, optimism, happiness, and self-determination" (Seligman and Csikszentimihalyi, 2000: p. 9).

As a logical consequence, the task of promoting positive emotions in children and adolescents was posed (Huebner and Gilman, 2003). The evidence obtained in the 2000s shows that a critical role in the success of children in school and in their social and emotional competence is played by self-regulation, in particular by controlling attention and inhibiting aggressive reactions.

The publications on positive psychology allow to distinguish the next factor that is beneficial to well-being; this factor is called 'mindfulness' (Kabat-Sinn, 2003). According to the definition given by Schonert-Reichl and Lawlor (2010), it is a way of directing attention. Generalizing a number of available definitions of this concept, mindfulness can be characterized as the ability to maximally proceed from the context while taking decisions in any situations. It is the ability to pay attention to many details while elaborating a decision, but not only 'mechanically' (e.g., by following a number of prescribed rules).

This explains why the ideas of the positive psychology movement have turned the attention of many researchers in the world to the models of development of CC during childhood.

The Levels of Consciousness Basic Model

It seems that the model proposed by Zelazo (2004) can be considered as a good working instrument for studying the development of CC during the first through fourth years of childhood. This model, called the levels of consciousness (LOC) model, emerged as a result of reflecting the experimentally discovered regularities of the development of CC of thought, action, and emotion. The model describes four transitions from one LOC to another, higher LOC; these transitions depend on age. Regarding the zero LOC, in the case of newborn babies and very young children aged up to 11–12 months, Zelazo (2004) characterizes the consciousness of this period as minimal consciousness; it is responsible for approach and avoidance behavior based on pleasure and pain and is present oriented, is unreflective, and doesn't operate with the self-concept.

The principal distinguished feature of LOC1 is the emergence of concepts and of the connections between the perceived objects and concepts (playing the role of labels of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23082-1

experienced objects). LOC1 is called by Zelazo (2004) the level of recursive consciousness. LOC2 emerges at the end of the second year; the essence of the transition from LOC1 to LOC2 consists in the emergence of symbolic thinking, in children's awareness of self. The signs of LOC2 are the first use of personal pronouns by children and their self-recognition in mirrors. Besides, children at this level feel the first self-conscious emotions, first of all shame.

LOC3 is called by Zelazo (2004) reflective consciousness 1; usually, this level characterizes the consciousness of 3-year-olds. The manifestation of this level is the ability of children to systematically use a pair of arbitrary rules (e.g., regarding objects of big size and of small size) for sorting pictures representing objects. However, the executive function of 3-year-olds is still limited, as was shown by experiments with the Dimensional Change Card Sort. For being successful in this game, children must integrate two incomparable pairs of rules into a single structure. This ability characterizes the LOC4, called by Zelazo (2004) reflective consciousness 2. Usually, LOC4 emerges by the end of the fourth year; this level is also characterized by a spectrum of metacognitive skills.

Expansion of the Levels of Consciousness Basic Model by the Theory of Dynamic Conceptual Mappings

The Necessity of Early Children's Socialization in Information Society

A number of phenomena caused by information and communication technologies (ICT) can be interpreted as negative shifts in the development of the personality in information society. A considerable part of information distributed via the Internet is false, but this false information is 'injected' into the net by concrete people. Very many high school and university students don't feel the value of a thought generated by another person and, as a consequence, use in their works the ideas, methods, and models belonging to other people. Acting in this way is very easy, because even by middle grades students possess well-developed skills in using e-mail, the Internet, and cell telephones. However, they are not socially mature and are not ready to suffer all the consequences of their deeds.

A new, tragic phenomenon of information society is cyber-bullying. Cell telephones, profile home pages, and social networking services are breeding grounds for cyber-bullying in some countries. Other negative deeds are attacks of young hackers against computer systems of socially very significant objects and military objects.

The common reason for all considered negative deeds is that children possess very high skills in using ICT but are very far from being socially mature and, as a consequence, far from being aware of their own social responsibility. Young children and adolescents usually can't clearly understand the severity of their actions when they are many times multiplied by the power of modern ICT.

That is why Fomichov and Fomichova (2012) believe that a possible way out is to elaborate methods of much earlier socialization of the child than are usually done in order, on one hand, to eliminate or considerably diminish children's aggressiveness, and, on the other hand, to contribute to the birth in children of feeling social responsibility and of understanding the severe consequences of their actions suffered by their peers and adults.

Shortly about Three Additional Levels of Consciousness Development

It seems in this connection that the broadly felt necessity of promoting children's emotional and social competence in schools and the lack in the scientific literature of rather simple solutions to this problem (see Schonert-Reichl and Lawlor, 2010) are the grounds for putting forward the following conjecture: the LOC model proposed by Zelazo (2004) indicates only some basic stages of consciousness development. The goal of creating appropriate theoretical foundations for promoting children's emotional and social competence will lead to discovering additional, higher stages of children's consciousness development corresponding to mature emotional and social competence of the child.

Realizing this idea, let's give a new interpretation of the methods of developing CC of thought, action, and emotion described in Fomichov and Fomichova (1997, 1998, 2006, 2012), Fomichova (2009), and Fomichova and Fomichov (2009). We'll suppose that these methods underpin the transition from LOC4 to LOC5, from LOC5 to LOC6, and from LOC6 to LOC7. The new levels LOC5, LOC6, and LOC7 will be called, respectively, the level of broad beauty appreciation, the level of appreciating the value of thought, and the level of enhanced awareness of social agreements and social responsibility.

A very short, preliminary description of these levels is as follows. Reaching LOC5 by the person means that this person possesses a well-developed feeling of beauty in various manifestations: the beauty of a thing, of an idea, of an expression, of a picture or sculpture, of interpersonal relationships, and so on (Fomichov and Fomichova, 1997, 1998; Fomichova, 2009; Fomichova and Fomichov, 2009). The successful transition from LOC5 to LOC6 means that (1) a child is aware of the fact that his or her ideas may be socially significant (i.e., the child may be appraised by peers or adults for the originality and beauty of his or her ideas), and (2) a child appreciates the value of the thoughts of other persons (Fomichov and Fomichova, 2006; Fomichova and Fomichov, 2000). Reaching LOC7 by a person means that this person is sufficiently mature in the social sense (i.e., possesses an enhanced awareness of social agreements and social responsibility) (Fomichov and Fomichova, 2012).

It should be underlined that modern preschool and school educational systems in various countries encourage only a rather small proportion of children to reach the fifth, sixth, and seventh levels of CC. However, to considerably increase this proportion is vitally important for the successful socialization of children in information society. Happily, at least one broadly applicable way of solving this problem has been available since the 1990s; it is outlined in this article.

About an Informational-Aesthetic Conception of Developing a Cognitive-Emotional Sphere in Learners

The methods underpinning the mindfulness-based educational interventions allowing for reaching the fifth, sixth, and seventh LOC development form an original approach to developing positive qualities in children and to early socialization of children. This approach is provided by the System of the Methods of Emotional-Imaginative Teaching (EIT-system). The core of the EIT-system was elaborated by O.S. Fomichova in the first half of the 1990s and has been expanded in the second half of the 1990s and in the 2000s. This system is underpinned by the Theory of Dynamic Conceptual Mappings (the DCM-theory), which was developed in the 1990s and 2000s by V.A. Fomichov and O.S. Fomichova. This theory is stated in numerous publications in both English and Russian, in particular in Fomichov and Fomichova (1997, 1998, 2006, 2012). The main component of the DCM-theory is an original informational-aesthetic conception of developing the cognitive-emotional sphere (in particular, emotional intelligence) of the learners: young children, adolescents, and university students. The central ideas of this conception are as follows:

1. It is important to actively develop a broad spectrum of information-processing skills of the child, starting at least at the age of 5. It applies, in particular, to associative abilities, the skill of integrating information from various sources, and the ability to establish time-causal relationships between events.
2. It is very important to combine the development of information-processing skills with inscribing, in a systemic way, the feeling of beauty into the world conceptual picture of the child.
3. Passing ahead the development of soul in comparison with the development of reasoning skills. A well-developed feeling of beauty plays an especially significant role in the realization of this idea. Besides, it is very important to be aware of the fact that children should have enough time for the development of soul: the time for contemplation, for imbibing the beauty of nature, and so on (i.e., children should have time for self-paced activity).
4. The principal cognitive precondition of successfully (as concerns a long-term perspective) acquainting children with computers is the realization of the thought-producing self of the child. It is a new concept expanding the collection of self-concepts considered in psychology. This concept means that the child should know that his or her thoughts may have a high social significance, that is, be appreciated by his or her peers, parents, grandparents, teachers, and so on (see Fomichova and Fomichov, 2000; Fomichov and Fomichova, 2006). The child should be aware of this fact before the time when adults start to systematically acquaint him or her with computers.
5. Due to mastering modern ICT (cell telephones, the internet, etc.), the consequences of children's negative actions may be very severe. That is why it is necessary to find ways of socializing children in the modern information society much earlier in order to eliminate or considerably diminish their aggressiveness and to contribute to the realization by children of the real scale of their misuse of ICT.

The Maps of Cognitive Transformations

Let us use a new graph notation allow to reflect the initial and achieved states of the cognitive-emotional sphere of the learner (Fomichov and Fomichova, 2012). This notation will be used in this article for describing the new methods of developing CC.

By definition, *a map of cognitive transformations* (MCT) is an oriented graph with the vertices of three classes (or types). The *A-vertices* are represented by the rectangles (or blocks) with the *single contour*; the texts inside these blocks describe the theoretical materials underpinning the teaching methods. The rectangles corresponding to *B-vertices* have the *double contour*; the text inside these rectangles describes the activity at a lesson (or lessons) either of a teacher or of the students. The *C-vertices* are represented *by the ovals*; the text inside these ovals describes the initial or achieved state of the cognitive-emotional sphere of the learner or the state of the spectrum of the learner's cognitive skills. **Figures 1–3** commented on in this article are examples of MCT.

The Level of Broad Beauty Appreciation

Initial Steps of Developing Conscious Control of Thought and Emotion

The EIT-system proposes a complex series of educational interventions aimed at reaching the consciousness level of broad beauty appreciation. An MCT realized at this stage is presented in **Figure 1**.

One of the distinguishing features of the approach to this problem is that it is realized in lessons for a foreign language (FL) – English – when the mother tongue of the children is Russian. The use of original, specially invented analogies (being the parts of fairy tales and thrilling stories) for teaching the English alphabet, the rules of reading, and the basic rules of English grammar contributes to developing associative abilities of children at the ages of 5–6.

Example. A difficult problem is to explain to very young children why the verbs in the third person of past simple tense have no 's' ending , but the same verbs in the third person of present simple tense do have such an ending ('reads' but 'read,' etc.). An interesting story from one of the previous lessons associates the 's' ending with a bow. The teacher explains that her young students were, in the past, babies and had no hair (were bald). Hence, it was impossible to tie a bow. That is why the verbs have no 's' ending in the third person of past simple tense. Five-year-old students accept this explanation with great joy and remember it very well. As a result of having heard stories of the kind, children become aware of the fact that symbolic objects have meanings pertaining to real or fairy-tale life.

These interesting stories about the life of verbs and other words establish in the consciousness of the young child

Figure 1 The map of cognitive transformations corresponding to the basic stage of developing creativity and broad beauty appreciation.

Figure 2 The map of cognitive transformations realized for achieving the level of appreciating the value of thought.

a mapping from the objects and situations of real life to the domain of language entities (verbs, nouns, pronouns, etc.). That is why the consciousness of the young child receives a considerable impulse to develop the ability to establish diverse analogies.

The next steps are as follows (see also Fomichova and Fomichov, 2009):

- reading and discussing complex texts in English as a foreign language (FL) at the ages of 5–6;
- mastering a rich sublanguage of FL for expressing the beauty of nature and the feelings evoked by nature;
- developing figurative reasoning + developing awareness of the social role of natural language;
- understanding poetical metaphors;
- creating metaphors;
- understanding the symbolic language of painting;
- developing the ability to decode the messages conveyed by the masterpieces;
- realizing the "Thought-Producing Self" (Fomichova and Fomichov, 2000) and the improvement of the feeling that a person is a link in the long chain of previous and future generations.

A Discovery: The Consciousness of 5–6-Year-Olds Needs a Very Beautiful Language

The principal reason for using the lessons of FL for positively developing CC is that (as a 23-year-long experience has shown)

Figure 3 The map of cognitive transformations realized for achieving the level of enhanced awareness of social agreements and social responsibility.

young children learn beautiful language constructions for describing their impressions from nature easier in FL than with equivalent constructions in their mother tongue (Fomichov and Fomichova, 1997, 1998). The explanation of this phenomenon is that in this case, children don't feel any contradiction with the everyday use of language.

Proceeding from a 7-year experience of teaching more than 300 young children, Fomichov and Fomichova (1997, 1998) formulated the following conclusions. The deepness, brightness, and amplitude of the emotions of average 4–9-year-old children (i.e., children of usual, average abilities) evoked by pictures of nature are much stronger and higher than is generally accepted or believed in modern science and education. As a consequence, the consciousness of the 4–9-year-old child is open to mastering a very rich, very beautiful sublanguage of natural language enabling the child to adequately describe pictures of nature and the emotions evoked by such pictures. Average 5–9-year-old children master very easily, and with great joy, very rich language means for describing pictures of nature, landscapes, and seascapes. The reason for this ease and joy is that the learning of such rich language means deeply corresponds to the demands of the child's consciousness at that very important period of his or her development. These conclusions were confirmed by the experience of using this approach in the 2000s.

Example. Let's consider a fragment from the home composition "The Winter Day," which was written in English by a 6-year-old Russian student, Kseniya, who was in the second year of studies in the experimental groups (Fomichov and Fomichova, 2012: p. 124):

> In the picture I see a winter day. On the branches of fir-trees, pine-trees, and birches lies fluffy, white snow, glimmering in sunshine. It seems that snowdrops are covered with jewels. Near the wood there are fields with snow. On the edge of the snowfield the rill is dreaming. The snow is everywhere. Sunrays make one way through the grey, big, heavy clouds and run over top-trees. Pine-trees and fir-trees shine hoary green. The bare bushes of birches are covered with snow. It seems that the oak is with soft, white, and big leaves.

> Suddenly someone in heaven has dashed a big cup of sunlight upon the Earth, and the big old oak has turned into a fairy King in orange magnificent gown. And around him young birches in nice gowns are accompanying their beloved King.

The Level of Appreciating the Value of Thought

A system of values underpins a human being's conceptual picture of the world. Regarding thought as a value causes a more careful attitude toward language, because it is a tool for thinking; and arouses interest toward metaphors, because the construction of metaphors creates new images, makes the world brighter, and introduces beauty into it. One of the principal objectives of educational interventions at this stage is to enable the child to really hear one's partner in communication, because it is a significant precondition of successful socialization. Figure 2 illustrates the basic steps of a method proposed by the EIT-system.

The Level of Enhanced Awareness of Social Agreements and Social Responsibility

The method of reaching the seventh level of consciousness development proposed by Fomichov and Fomichova (2012) proceeds from the central idea of Searle (1995) about the natural language as the primary means of constructing social reality, and it considerably expands and works out in detail this idea.

The Steps of the Method

Taking into account the existence of the negative phenomena discussed in this article, the following new objectives for

influencing the development of the personality in the modern information society can be formulated. It is necessary to start earlier than is traditionally done to acquaint children with the very complex system of social agreements. Since this system is based on numerous symbols, scholars need to pay more attention to developing the symbolic information-processing skills of young children and teenagers. In addition, it is necessary to acquaint children early with the idea that different people may have considerably different inner-world pictures (i.e., conceptual systems), and it is very important to take this into account while interacting with people. It is important to explain to young children and teenagers that practically every person has various connections with many other people. That is why the suffering of a classmate or the like, in fact, causes the suffering of many other people: mother, father, brothers, sisters, grandmother, grandfather, and so on.

Figure 3 represents the basic components of this method. The central idea of the method is as follows. Rather often, a child tries to distinguish himself or herself among his or her peers by means of emulating a bad pattern of adult behavior: smoking, aggressiveness, following the formula of 'might is right,' and so on. This applies not only to teenagers but also to children at the ages of 10–11. It is important to underline that the bad patterns of adult behavior (drinking, etc.) most often are the consequence of misfortune or despair. Normally, children have no despair; they simply emulate the adults.

As a result, however, of employing the stated method at lessons under the framework of the EIT-system, the child acquires (by the end of the second year of studies, at the age of 6–7 years) the possibility to distinguish himself or herself not by means of a deviant behavior but with the help of mature thoughts and thoughtful behavior.

A New Way of Supporting a Balance of Conscious Control and Creative Imagination

Carlson (2010), in particular, formulates a paradox of CC: the enhancement of CC causes restrictions for the imagination and creativity of the learners. According to this logic, the approach to early socialization of children described here must diminish the creativity of the learners.

Happily, this is not true as concerns the EIT-system. This educational program manages to maintain a good balance of enhanced CC and creativity due to an original way of teaching young children to appreciate the value of thought and to realize their Thought-Producing Self. As was described in this article, it is the principal feature of LOC6, an advanced level of consciousness development. Due to this approach, children follow social agreements in standard situations of communication but are highly creative while solving posed tasks, in particular while inventing metaphors.

The System of Emotional-Imaginative Teaching as an Original and Well-Tested Approach to Constructing Mindfulness-Based Educational Programs

The Goals and Composition of the System

Retrospectively, it is clear that the first mindfulness-based educational program was created approximately 10 years before the birth of the term 'mindfulness.' This program was provided by the EIT-system. As was mentioned in this article, the core of the EIT-system was elaborated by O.S. Fomichova in the first half of the 1990s and was expanded by O.S. Fomichova and V.A. Fomichov in the second half of the 1990s and in the 2000s.

The principal goal of the EIT-system is to develop in young children and teenagers:

- skills in processing symbolic information and in reasoning abilities;
- a mature, rich, cognitive-emotional sphere, and the ability to perceive and appreciate beauty in all of its manifestations, in particular in the deeds and relationships of people;
- the ability to understand the peculiarities of the world conceptual picture of one's communication partner;
- an understanding of the complex system of social agreements;
- the skill of grounding one's own point of view and of participating in a dialogue;
- the feeling of belonging to a very long chain of previous and future generations as the principal cognitive precondition of sustainable development; and
- the state of being open to the achievements of both national and world culture.

For achieving these listed objectives, a collection of the interrelated educational methods and an original cross-disciplinary educational program have been developed by O.S. Fomichova. The program is intended for teaching children for 12 years, where the starting age is 5–6 years. The program has been personally tested in Moscow with great success by O.S. Fomichova over a period of 23 years. The total number of successfully taught students exceeds 900. The program includes the following series of lessons: (1) a 2-year course (the ages of the learners are 5–7 or 6–8 years) of studying the foundations of reading and speaking English as an FL, including learning basic elements of English grammar (present simple and past simple tenses); (2) a course on understanding the language (a part of FL) of describing nature and feelings evoked by nature; (3) a course on understanding the symbolic language of painting; (4) a course on understanding the language of poetry (with the accent on understanding metaphors and descriptions of nature); (5) a course aimed at first acquaintance with sciences and developing the abilities to argue one's own opinion, raise objections, and so on; (6) a course on improving knowledge of English grammar (mainly during the fifth year of studies); and (7) a course entitled "Foundations of Secure Living in Information Society." In fact, the lessons of courses (2) to (7) may interchange.

The developed program can be interpreted as an original model of a system of disciplines traditionally learned in school (elementary, middle, and high) and in the courses forming the humanitarian component of a university education.

A Broad Applicability of the EIT-System

The EIT-system has been mainly realized in lessons of English as an FL for Russian-speaking children, in lessons of poetry and literature in English, and in lessons devoted to explaining the symbolic language of painting, the culture of communication,

and the symbolic language of classical dance. These kinds of lessons are considered in numerous countries as highly appropriate for young children and teenagers. A carefully selected collection of texts used at lessons is provided by a number of classical, world-renowned fairy tales and novels, in particular 'Snow White,' 'Cinderella,' 'Sleeping Beauty,' 'Pinocchio,' 'Pollyanna,' 'The Life and Adventures of Santa Claus' by L. Frank Baum, 'Alice in Wonderland' by Lewis Carroll, 'The Wind in the Willows' by Kenneth Grahame, 'The Hundred and One Dalmatians' by Dodie Smith, and others. That is why the EIT-system may be used (after a certain adaptation requiring a small time) in English-speaking countries and in numerous countries where English is learned as a second language.

Abstract

In this article, we give an overview of the search for the neural correlates of consciousness (NCCs). We begin with a discussion of the conceptual complexities of defining the notion of an NCC. We then discuss some of the experimental approaches used to empirically investigate the NCCs. We then consider some competing views of NCCs. Finally, we consider how the competing views of NCCs bear on different theories of consciousness. We focus on the methodological and theoretical challenges facing this line of research.

Introduction

The study of consciousness is one of the biggest challenges for scientific explanation. Whatever such an explanation will be – to the extent that one is possible – it will no doubt require an empirical theory of the neural processes thought to give rise to the subjective qualitative nature of conscious experience. If you are reading this article you are no doubt acquainted with the phenomenon of consciousness. But though nothing could be more familiar than one's first-personal phenomenal experience of the world, we will see that the scientific study of consciousness faces some serious methodological challenges.

It will be useful to begin with the distinction between information processing and subjective experience. Consider the mundane example of looking at a glass of red wine sitting on a table before you. Light bounces off the surfaces of the glass and table and reaches your eyes. Invariably some information is lost since the light coming off the three-dimensional scene generates two distinct two-dimensional images each of which is recorded by one of your retinas. Your visual system is faced with the task of combining these two different images to recover the lost information needed to generate a representation of the three-dimensional scene before you. This is a tractable albeit complex information processing problem with a computational solution (Marr, 1982). Cognitive neuroscience has made great strides in studying the brain as a complex information processer. But the brain does more than just information processing. It also generates a subjective experience of the mundane scene. The qualitative aspect of this experience – the feeling of 'what it's like' (Nagel, 1974) to have a visual experience such as a visual experience as of a glass of red wine in front of you – raises a multitude of scientific and philosophical questions: why should there be something it is like to experience the scene? That is, why should the physically realized system that solves the information processing problem also give rise to a subjective experience? And how does it do so? These questions are at the core of the so-called hard problem of consciousness (Chalmers, 1996). What scientific progress can be made on these questions is controversial. There is, however, a related question that is well-suited for scientific inquiry. That is, what are the neural processes and states that are correlated with states of consciousness? While this is an important question in its own right, the hope is that studying the neural mechanisms that are correlated with such states and process might illuminate the hard problem as well (Crick and Koch, 2003).

In what follows, we begin by considering some of the conceptual intricacies of explicating the notion of a neural correlate of consciousness (NCC). We then consider some experimental approaches. We then turn to look at some competing views of NCCs, and the methodological problems that arise in formulating such theories. We then consider how the competing views of NCCs bear on different theories of consciousness.

What Is an NCC? Preliminary Conceptual Issues

The Neural Correlates of Conscious vs Unconscious States

On a first pass, the question of what are the neural correlates of consciousness could be interpreted as the following: (1) which neural states and processes must be active for a subject to be conscious at all? We can distinguish this question from the following: (2) which neural states and processes must be active for a subject to be in a conscious state with some particular content? (1) and (2) can be distinguished by their respective taxonomies of conscious states. (1) is thought to address the background or enabling conditions for consciousness. When these conditions fail to obtain we should expect an absence of consciousness. For example, Bogen's (1995) proposal regarding the function of the intralaminar nuclei of the thalamus is directed at (1). The basic distinction that (1) attempts to track is the difference between conscious and unconscious states. But as Baars (1988) points out there are two major components to consciousness: 'wakefulness' and 'awareness.' Wakefulness is thought to track the level of consciousness (also described as arousal). Awareness tracks the notion of the subjective experience of consciousness. In general one needs to be awake to be aware (though dreaming in rapid eye movement (REM)-sleep is thought to be an exception). Patients in pathological coma or under general anesthesia are considered unconscious because they cannot be awakened. An interesting and ethically relevant line of research concerns cases where wakefulness and awareness are dissociated. One such case is the vegetative state where patients seem to be awake but lack awareness. As Steven Laureys points out, since

we cannot use behavioral measures to differentiate vegetative from minimally conscious patients – that is, patients with some awareness – the use of functional magnetic resonance imaging (fMRI) and positron emission tomography (PET) imaging studies are crucial, though much more work needs to be done before negative results from such studies can be taken as evidence for lack of awareness (Laureys, 2005).

The Neural Correlates of the Contents of Consciousness

Much of the current research on NCCs has been directed at (2), particularly in the visual modality. The goal of this research is to reveal the NCCs of particular types of conscious states, where conscious state types are individuated in terms of their contents. This provides a more fine-grained way of individuating conscious states. If some neural structure N is directly correlated with some conscious state C, where C is individuated in terms of particular contents of consciousness, then if N is active, we should expect a subject that realizes N to be in a state with those particular contents.

Research on the neural correlates of particular contents of consciousness suggests the need for a further refinement of our notion of an NCC. The focus of this research is on finding the minimal sufficient neural correlate for a content of consciousness. If some neural state N is minimally sufficient for a correlated conscious state C, then there will be no proper part of N that is sufficient for C. Without this restriction, we can trivially satisfy the search for the neural correlate of a conscious state by simply pointing to the total state of the brain at the time that the conscious state occurs. Chalmers (2010) points out that the notion of a minimally sufficient NCC requires making a distinction between a 'total' minimally sufficient NCC and a 'core' NCC. For example, the proposed neural correlates of the phenomenal experience as of a face (discussed below) are thought to lie in the 'fusiform face area' (FFA) (Kanwisher, 2001). But the FFA is not a minimally sufficient neural system whose activation guarantees the conscious experience as of a face. The notion of an NCC operative in this line of research is what Chalmers calls a 'core NCC.' The core NCC of a conscious state C with the phenomenal content as of a face (for example), is the part of the neural basis that distinguishes C from a conscious state C,' with different phenomenal content. The search for a core NCC requires distinguishing core processes from background process that make up a total minimally sufficient neural system. Chalmers suggests that drawing the distinction between total and core NCC requires specifying the relevant range of cases over which the correlation holds, given certain normal brain-functioning conditions.

Considering these conceptual distinctions in the abstract of specific views of NCCs can be difficult. We now turn to look at some specific examples of work on NCCs. Doing so will help bring these issues in contact with current research.

Experimental Approaches

Some considerable progress has been made in the search for the neural correlates of the contents of consciousness. One such line of research has pursued the core neural correlates of the visual experience as of motion. Both fMRI studies on human subjects, as well as electrophysiological recordings, and lesion studies in nonhuman primates suggest that the middle temporal visual area is correlated with the subjective experience as of motion (Heeger et al., 1999; Newsom and Paré, 1988). The empirically grounded assumption that humans and nonhuman primates have homologous sensory systems makes it possible to use single-cell recordings data from nonhuman primates to formulate more fine-grained hypotheses about the locations of the neural bases of particular contents of consciousness. The hope is that this will lead to a better understanding of how the activity of particular neuronal populations plays a role in generating the specific contents of a conscious experience.

Another example of research on the core neural correlates of particular contents of consciousness can be found in the work of Kanwisher and colleagues (mentioned earlier). Drawing on data from fMRI scans in a binocular rivalry stimulus condition and stimulus alternation condition, Kanwisher argues that the correlation of neural activity in the FFA and the subjective experience as of faces suggests that FFA plays a role in the awareness of faces in particular, as opposed to playing a role in perceptual awareness generally (Kanwisher, 2001).

The binocular rivalry paradigm is used to generate bistable percepts, in which constant retinal stimulus generates alternating percepts. fMRI scans of humans as well as single-cell recordings in nonhuman primates make it possible to monitor neural activity patterns during alternating percepts. Logothetis and his colleagues conducted a series of seminal experiments using a binocular rivalry paradigm along with single-unit recordings in macaques. The macaques were trained to pull a different lever in response to each of the alternating percepts in the binocular rivalry condition. Logothetis and colleagues repeated this paradigm for various contrasting stimuli pairs such as sunbursts and faces, and gratings with contrasting direction of orientation. The physiological recordings from such experiments showed that activity in primary visual cortex was not well correlated with a change in percept. However, in higher visual areas such as inferior temporal cortex, almost all neurons responded only to a preferred stimulus when that stimulus was perceptually dominant. (For an extensive review of a variety of such experiments see Logothetis, 1998.)

Competing Views of NCCs

We now turn to some competing views of NCCs and the methodological difficulties raised by such views. Due to space limitations, we focus mainly on the current major contenders for the NCCs of visual awareness, at the level of whole-brain functional anatomy. One advantage of focusing on this level of analysis is that the different views turn out to support different theories of consciousness, as we will discuss in the next section. Though we look specifically at the case of the NCCs of visual awareness, we expect that many of the points will generalize to the analogous debates over the NCCs of other sensory modalities such as audition. The analogous views in the case of audition would consider the role of early

auditory areas, where the views below discuss the role of early visual areas.

The Global View: Frontoparietal Network Plus Extrastriate Correlates

We begin with considering three claims, the conjunction of which make up what we'll call the 'Global' view of the NCCs of visual awareness. These are: (1) the primary visual cortex (V1) may be necessary for visual experience but the representations in V1 are not sufficient to give rise to specific contents of consciousness, conscious experience is thought to be generated further upstream; (2) the specific contents of consciousness are represented in the various relevant extrastriate areas, (such as the (FFA) for the conscious experience as of a face discussed above); and (3) activity in the prefrontal and parietal cortices is an enabling factor, which is essential for visually conscious states. The conjunction of (1)–(3) is a popular view that has garnered support from a number of high-profile imaging studies (Sergent and Dehaene, 2004).

We can start to see the contours of one aspect of the debate over the NCCs of visual awareness by comparing two alternative views that differ with respect to claim (3) above. The first alternative we look at rejects (3), and can naturally be extended to support a further distinction between phenomenal consciousness and cognitively accessible consciousness. The second view embraces (3), and holds that most of what has been claimed to be the neural correlates of consciousness in fact reflects signal strength or performance capacity, but not conscious awareness per se. This criticism suggests a distinction between stimulus awareness and subjective awareness.

Visual Activity Only View

Proponents of what we call a 'Visual Activity Only' view argue that activity in the prefrontal and parietal cortices are not essential to visual awareness. Rather these areas reflect associated processes such as attending or cognitive access for the purpose of reporting on the contents of visual experience (Block, 2005, 2007; Lamme, 2006; Macknik, 2006).

Block (2005, 2007) has suggested a distinction between what he originally termed phenomenal consciousness and access consciousness (Block, 1995). Phenomenal NCCs determine the contents of experience. But the phenomenal contents of consciousness are not necessarily cognitively accessible. Contents that are cognitively accessible are contents that are available to the brain's 'consumer' systems. Consumer systems are systems such as reasoning, planning, decision-making, voluntary direction of attention, and systems for rationally controlled action (Block, 2005). Here, we appeal to Block's refined view in which he claims that cognitive accessibility is not constitutively necessary for phenomenal consciousness (extensively defended in Block (2007)). The claim is germane to the current discussion since it highlights important methodological difficulties in the search for the neural correlates of consciousness.

Block defends the claim on both conceptual and empirical grounds. According to Block it is possible that there are modularly encapsulated representations that are inaccessible to report, but may very well be phenomenally conscious. The possibility raises a methodological puzzle for consciousness research. Ideally, we would pursue the question by identifying the neural basis of phenomenal consciousness in clear cases where we are confident that a subject is phenomenally conscious, and then look to see whether this neural machinery is active in cases of encapsulated representations. The methodological puzzle arises since the 'clear cases' will be ones where subjects report having a phenomenal experience and there are no empirically grounded reasons to doubt these reports (as there are in the case of Anton's blindness). But the neural correlates of these clear cases will invariably include the neural mechanisms underlying cognitive accessibility, since the total neural basis of a state with phenomenal consciousness C is itself sufficient for the instantiation of C. So the method would require already having a way to distinguish between the neural bases of cognitive accessibility and phenomenal consciousness. Block points out that it is cognitive accessibility not reportability that is at issue since we have reasons to think that subjects with locked-in syndrome or profound global aphasia (or both) still have phenomenal experience (Block, 2007).

Block's positive view could be considered a species of what we called the 'Visual Activity Only' view. On Block's view, cognitive accessibility is likely supported by prefrontal mechanisms, which are typically associated with higher-level cognition. He argues that sensory representations of the right kind in early visual areas are phenomenally conscious, but they are only cognitively accessible when they are propagated into the prefrontal circuitries. Part of the motivation for this view is that early visual processing is known to have higher informational capacity and spatial resolution than processes in the prefrontal cortex. Therefore, if cognitive access depends on prefrontal mechanisms, and phenomenal consciousness is supported by early visual activity, one can explain why phenomenal consciousness seems to 'overflow' access: that is, we may subjectively experience vivid details more than we can report or access. As evidence for the overflow of phenomenal experience, Block cites the results of Sperling's famous partial-report paradigm (Sperling, 1960) and similar studies (Sligte et al., 2008), as well as a study by Landman et al. (2003), which combines a change blindness paradigm, with the original Sperling paradigm. In the original Sperling paradigm, subjects are shown an array of alphanumeric characters for 50 s followed by a blank screen. Subjects report the subjective experience of having seen all or almost all the characters. However, when subjects were asked which characters they had seen they were typically able to report only three or four characters out of a three by four array. When trained with three different tones to cue the three different rows, subjects showed they were able to report all or almost all the characters of any given row, even though the cue appeared only after the array disappeared. The fact that subjects could do this for any one of the rows supports their subjective reports of having 'seen' all the characters. These studies suggest that only a small subset of what subjects experience is cognitively accessible to report.

Koch and Tsuchiya (2007b) have suggested phenomenology without cognitive access is an example of consciousness without top-down attention. According to Koch and Tsuchiya, empirical evidence that consciousness and top-down, volitionally

controlled endogenous attention are distinct neurobiological processes, supports the distinction between phenomenal consciousness and cognitive accessibility (Koch and Tsuchiya, 2007a,b; Tsuchiya and Koch, 2008). However Koch and Tsuchiya (2007b) seem to differ with Block methodologically in the role of subjects' denials of phenomenal experience. Their discussion suggests that a subject's introspective report (in the absence of compelling evidence to the contrary) should be 'accepted as brute fact.' While their work on the dissociation of top-down mechanisms and phenomenology supports Block, that work does not directly bear on the question of whether current fMRI studies can be used to show that phenomenal consciousness should be attributed to subjects in some of the cases where subjects deny having any phenomenal experience.

Prefrontal Only View

This view locates the essential neural basis of consciousness in later prefrontal and/or parietal areas. This is not to say that proponents of this view think that a state could be visually phenomenally consciousness without input from early visual areas. Rather the view claims that early visual activity alone is not sufficient, and that the subjective aspects of conscious experience are determined by prefrontal and parietal processes. In this sense, this view is similar to the Global View. The critical difference is that according to the Prefrontal Only view, much of early visual (including extrastriate) activity as well as prefrontal and parietal activity just reflects the perceptual signal, which is important for task performance capacity but does not reflect the essentially subjective aspects of conscious perception. If we control for task performance capacity (i.e., by keeping it constant), a difference in subjective conscious perceptual experience may be correlated with a difference in activity in relatively restricted areas in the prefrontal (and possible parietal) areas.

One motivation for this view is that clinical phenomena like blindsight demonstrate the dissociation between subjective reports and task performance. That is, such patients report having no phenomenal experience of a stimulus despite being able to perform well above chance in tasks such as visual discrimination (Weiskrantz, 1986, 1997, 2004). Neuroimaging findings (Persaud et al., 2011; Sahraie et al., 1997) as well as computational modeling (Ko and Lau, 2012; Pasquali et al., 2010; Timmermans et al., 2012) support the idea that when we control for task performance the subjectively reported conscious experience is associated with prefrontal activity.

Lau and Passingham (2006) have demonstrated that this dissociation occurs in normal-sighted subjects as well. They used a metacontrast paradigm to match task performance in subjects' discrimination of two targets in two conditions. Subjects were asked to make a forced-choice as to whether the target was a square or a diamond. Immediately after the forced-choice, subjects were asked to indicate whether they saw the target or simply guessed. Performance difficulty as measured by reaction times was also very similar across the two conditions. Though the two conditions were matched for discrimination performance, they yielded a difference in the frequency of subjects' reports of visual awareness. Comparison of the associated neural activity for the two conditions using fMRI showed a difference in activity in the dorsolateral prefrontal cortex (DLPFC). Notably, Lau and Passingham were unable to find a difference in the visual areas across the two conditions. In a further study, transcranial magnetic stimulation (TMS) application to DLPFC showed a similar finding. Task performance was matched in both TMS and non-TMS application trials, but subjective ratings of visibility differed between the two conditions (Rounis et al., 2010).

Theoretical Implications of the Different Views of NCCs

Global Theories of Consciousness

Many have taken the first view (i.e., the Global View) of the NCC as support for a certain class of theories consciousness. Most prominently, the Global Workspace Theory proposed by Baars (reviewed in 2005), and later developed in neuronal terms by Dehaene and colleagues (Sergent and Dehaene, 2004), would predict results similar to those of the Global View of NCCs. According to the global workspace theory, there exists a central broadcasting mechanism that allows the flexible and global exchange of information between peripheral modules (such as early vision, low level motor processing, and memory). When information enters this workspace, it becomes conscious, and is globally broadcasted to all modules and, therefore, all subsystems can share and edit such information. Dehaene and colleagues specifically hypothesize that the workspace depends on neurons in the prefrontal and parietal areas. It is not entirely clear whether all global theorists hold that early visual activity is necessary. That is, such an activity could be the normal cause that leads to global activity in the prefrontal and parietal cortex, which in turn is necessary for consciousness. Or, alternatively, the early visual activity as well as the activity in prefrontal and parietal cortex are both necessary.

Local Theories of Consciousness

If it turns out to be true that the visual NCC consists of only activity in the posterior visual areas in the brain, theories other than the global workspace would be supported. Block (2005, 2007) for instance, put forward what he calls a 'biological' theory of consciousness, according to which phenomenal visual awareness depends on specific biological substrates in the posterior visual areas in the brain. Note that the global workspace theory as characterized above does not make the distinction between phenomenally conscious contents and cognitively accessible conscious contents. Block's theory and the global workspace theory are often seen as in competition by those who claim that phenomenology that is not accessible should not be considered conscious at all.

Lamme (2006) similarly argues for the need to dissociate consciousness from other cognitive functions, such as attention, working memory, and reportability. On his proposal, visual awareness depends on local feedback loops within the visual areas. By contrast, processing in higher areas is related to the dissociable cognitive functions.

Another theory of visual consciousness which would be supported by the Visual Activity Only view of NCCs is Zeki's

(2003, 2007) 'microconsciousness' theory. The 'microconsciousness' theory suggests that activity in the early visual areas is correlated with specific conscious percepts. On Zeki's proposal, consciousness is not a single unity but consists instead of many components – the 'microconsciousness' – distributed in space and time and which constitute a hierarchy.

The common thread of these theories is that the neural substrate that supports the processing of visual information itself is sufficient to generate a conscious percept, independently of the neural substrate that supports further processing in higher cognitive areas.

Higher-Order Representational Theories of Consciousness

If the Prefrontal Only view of the visual NCC is right, that would lend support to at least some versions of higher-order representational theories of consciousness. According to higher-order theories, in order to have a conscious experience, we need more than just the first-order representation, which has a representation as of some object as its content. On top of that, we need to have a higher-order representation that is about the first-order representation. There is some debate as to whether the content of this higher-order representation is similar to thoughts (Rosenthal, 2005) or percepts (Lycan, 1996), or perhaps that the higher-order representation and the first-order representation should not be counted as separate, but rather as parts of a single self-referential system (Kriegel, 2009).

Lau (2008, 2010) has put forward a different version of a higher-order theory. According to Lau, the higher-order representation simply enables statistical inferences or judgments of perceptual certainty. That is, given that the first-order representations are often corrupted by noise in the brain, the higher-order representation contains some statistical information that allows a judgment of the reliability of the first-order representation. Subjective visual awareness occurs when a percept is judged to be sufficiently reliable.

Higher-order theories, in general, are congenial to the results that a change in activity in the prefrontal and parietal cortices are sufficient for a change in conscious percept as suggested by the prefrontal enabler view. One would expect the higher-order representations to be in these brain regions, as they seem to play roles in uncertainty monitoring, cognitive control, thinking and planning, etc. Lau (2010) predicts that if one keeps the first-order representation constant, a change in the higher-order representations alone would be enough to change the character of a conscious experience.

This prediction is important since it may serve to distinguish at least some higher-order theories from the Global Workspace Theory. It is unclear whether the global workspace theory is committed to such predictions. In most discussions, one typically thinks that a visual signal (roughly equivalent to a first-order representation) enters the global workspace by being stronger than other competing signals. Therefore, when a visual percept changes from consciously seen to unseen, one would expect the difference to be reflected not only in the higher global workspace areas, but in the lower visual signals too. Also, it may be possible that when the signal enters the workspace, the global broadcasting sends feedback to the earlier visual areas, which would in turn mean that the conscious signal would end up becoming stronger in the early areas.

Since the workspace is supposed to be functionally important even when the first-order visual signal is matched, and somehow in one condition the signal gets into the workspace and in another condition it does not, one would predict big behavioral differences, such as that in one condition the visual targets are better identified or reported. However, Lau's higher-order theory would expect that there can be few functional differences in terms of discrimination or identification of the target, if the first-order signal/representation is matched. A difference in higher-order representation leads to a difference in visual awareness, and the only accompanying behavioral difference is the judgment of perceptual certainty.

Concluding Remarks

The foregoing discussion is just a sample of some of the complexities involved in the search for the neural basis of consciousness. We've reviewed some of the conceptual issues in explicating the notion of an NCC. We saw that the search for the minimally sufficient core neural correlates of particular contents require a distinction between background or enabling conditions of those NCCs and the NCCs themselves. We also noted that there are some empirical grounds for dissociating the phenomenological aspects of conscious experience from cognitive functions such as attention and access for the purpose of report. But making such distinctions and dissociations also raises some methodological difficulties. These difficulties suggest that the scientific search for NCCs is quite complex. Clearly, there is much more work that needs to be done. That work includes empirical investigation into the neuronal correlates of the contents of consciousness, as well as reflection on the methodological and explanatory tools needed to theorize about empirical results.

Consequentialism (Including Utilitarianism)

Philip Pettit, Princeton University, Princeton, USA; and Australian National University, Canberra, ACT, Australia

Abstract

Consequentialism is the theory that the way to tell whether a particular choice is the right choice for an agent to make or to have made is to look at the relevant consequences of the decision: to look at the relevant effects of the decision on the world. It gives rise to many questions. Some are general questions as to how more precisely the doctrine can be defined and defended, and as to what the main forms of opposition are. Others are in-house questions that go to matters of detail in the specification of the theory. This article offers an overview of positions on those questions.

Consequentialism is the theory that the way to tell whether a particular choice is the right choice for an agent to make or to have made is to look at the relevant consequences of the decision: to look at the relevant effects of the decision on the world. It gives rise to many questions. Some are general questions as to how more precisely the doctrine can be defined and defended, and as to what the main forms of opposition are. Others are in-house questions that go to matters of detail in the specification of the theory. This article offers an overview of positions on those questions.

Roughly speaking, consequentialism is the theory that the way to tell whether a particular choice is the right choice for an agent to make or have made is to look at the relevant consequences of the decision: to look at the relevant effects of the decision on the world. In directing us to consequences, the theory is teleological in focus; the term comes from the Greek word *telos*, meaning end or goal. It is opposed to any theory that does not make the consequences into the ultimate touchstone of rightness and wrongness in choices. The classical antonym is the deontological approach – this term comes from the Greek work *deon*, meaning obligation or duty – but there are other antonyms too, as we shall see. Where consequentialism would assess a choice by looking at its consequences, a deontological approach would assess it by looking at how the choice measured up to the obligations incumbent on the agent.

The Definition of Consequentialism

Nonconsequentialism comes in many forms. Deontologists hold that agents ought to discharge certain duties: They ought to tell the truth, keep their promises, be nonviolent, etc. Kantians say that agents ought to act on the categorical imperative – act only on a maxim that they could accept as a general law of behavior – or ought to treat other people always as ends, never only as means. Virtue ethicists say that they ought to manifest certain virtues in their behavior. Rights theorists maintain that they ought to respect certain rights that others have against them. Contractualists assert that they ought to conform to principles that no one could reasonably object to as the bases of social life. Theorists of special obligation say that they ought to deal in a certain way with those who are bound to them, such as their children, spouses, friends, and so on.

What is the common thread in these nonconsequentialist positions? All nonconsequentialists speak, at whatever level of abstraction, about what any or every agent ought to do or be; in that sense they are universalists. All prescribe neutral patterns of behavior or psychology or relationships: that people act on the categorical imperative, manifest certain virtues, respect the rights of their dependants, nurture their friendships, and so on. The patterns are neutral in the sense that they can be understood in the same way by everyone. And all say that the right thing for an agent to do is to instantiate the prescribed patterns – so far as they are coinstantiable – in their own behavior or psychology or relationships. In particular, they say that that is the thing to do even if instantiating a pattern in their own life means, because of the perversity of the agent's circumstances, that the pattern will be less fully realized than otherwise in the world at large.

Consequentialism makes a dual assertion in response to such positions (Baron et al., 1997). First, it asserts that there are certain potentially shared values by means of which possible states of affairs can be ranked, although perhaps not completely. These may be neutral patterns in human behavior or psychology or relationships, of the kind that the nonconsequentialist prescribes, or they may be neutral outcome patterns that are more detached from agency: patterns such as the maximization of human happiness or the saving of uninhabited wildernesses. And second, consequentialism maintains that the right choice for an agent to take in any decision is one of those choices, assuming there is at least one – assuming incomplete ranking is not a problem – that promotes the overall realization of such values or patterns (more below on what it is to promote values).

The basic difference, then, between consequentialists and their opponents is that while each side privileges certain general patterns – treats them as values, as it is natural to say – the consequentialist side says that the important thing is to promote the realization of those patterns in the world at large, while the opposing side says that the important thing is rather to instantiate the relevant patterns in one's own life: in one's behavior or relationships or psychology, or whatever. Consequentialists say that privileged patterns should be treated as consequences to be promoted, nonconsequentialists that they should be treated as constraints to be satisfied.

The difference between the two approaches is particularly salient for simple cases where only one pattern is taken to be relevant, and where there is no issue about the relative

importance of different patterns. Consider those cases, then, where nonviolence is assumed to be the only privileged pattern – the only value – that is relevant. And consider the different ways in which that pattern may be espoused among pacifists. The nonconsequentialist pacifist says that nonviolence is to be instantiated by agents, even if this means that there is more violence overall: even if violence spreads as a result of being unopposed. The consequentialist counterpart says that nonviolence is to be promoted overall, even if this means instantiating violence: say, waging the war to end all wars. In practice, the two sorts of pacifist will often converge in their recommendations, as nonconsequentialist Quakers converged with Bertrand Russell in their opposition to World War I. But there is always a possibility of their coming apart, as indeed those Quakers and Russell came apart in their attitudes to World War II.

Making the distinction between consequentialism and nonconsequentialism by reference to whether the agent is required to promote certain privileged patterns or rather to instantiate them – to honor them – is only one among a number of ways of making it. Another common approach is to distinguish between agent-neutral values and agent-relative ones, and to say that consequentialists advocate the promotion only of agent-neutral values, and nonconsequentialists the promotion of a mixed bunch or of agent-relative values only (Nagel, 1986).

Agent-neutral values are patterns that are identified without reference to who is doing the identifying: patterns like those involved in peace being achieved, happiness maximized, a wilderness preserved, and so on. Agent-relative values are patterns that are identified by back reference to the identifying person: patterns, to take the case where I do the identifying, like *my* doing my duty, *my* conforming to the categorical imperative, *my* manifesting certain virtues, *my* looking after my children, and so on. Where consequentialists advocate the promotion of agent-neutral values, and in particular agent-neutral values of a universal cast – they do not involve benefits just to a particular person or place or whatever – nonconsequentialists can be represented as advocating the promotion of agent-relative values: the promotion by every agent of *their* doing their duty, *their* conforming to the categorical imperative, *their* manifesting certain virtues, *their* looking after their children, and so on.

A Theory of the Right, Not a Theory of the Good

To say that something is good is to hold that it has a certain value, in particular a certain positive value. To say that something is right is to hold that among certain relevant alternatives – say, among the options in a choice – it is the one to have. And so rightness and goodness may come apart. An alternative that is wrong may yet be an object of great value; it may be wrong simply because another option is an object of even greater value. An alternative that is right, on the other hand, may not be something of great value; it may be right, simply because it is the least bad option among a very poor set of alternatives. A theory of the good, a theory of value, would enable us to determine the values of different entities. A theory of the right would enable us to determine, for any set of alternatives, which alternative or subset of alternatives is the right one.

When I speak of what is good, and of what has value, I have in mind an impersonal or agent-neutral conception of goodness and value. If I value a prospect for the increase of happiness it promises, or even for a particular effect it will have, say on planet Earth, then I value it agent-neutrally. If I value it for the benefits it will have for me or mine, or for the fact that it will keep my hands clean, or for any reason of that self-referential kind, then I value it agent-relatively. The theory of the good, or the theory of the valuable, refers to the theory of what is agent-neutrally valuable.

Does consequentialism present itself as a theory of the good or as a theory of the right, or as something involving commitments in both areas? By the account given, the theory is concerned only with the right, not with the good. It says that the right alternative in any choice is that which promotes the good, without making any commitment on the nature of the good. While it makes the right a function of the good, it says nothing in itself on the matter of what is good.

This aspect of consequentialism is often found surprising, as many people tend to identify consequentialism with utilitarianism. But utilitarianism involves a double commitment. It says that the good should be equated with happiness, whether this is understood in the sense of pleasure or preference satisfaction, and then it adds that the right alternative in any set is that which best promotes such happiness (Sen, 1979). Thus when G. E. Moore (1903) rejected utilitarianism, arguing that the good was not reducible to happiness – it was a nonnatural property that allowed of no such reduction – he remained a consequentialist about the right. Many contemporary consequentialists have nonutilitarian theories of the good or the valuable. Indeed they often look like nonconsequentialists to the extent that they may think that the good encompasses reflexive patterns, such as those involved in people generally keeping their promises, respecting those with whom they deal, or giving their children special attention.

Robert Nozick (1974), himself an outstanding nonconsequentialist, supports this view when he distinguishes between a nonconsequentialist theory of rights – a theory of rights, proper – and a consequentialism or utilitarianism of rights. The consequentialist theory of rights would say that it is good that certain rights are enjoyed generally, and it would imply that the right option in any choice is that which promotes the enjoyment of such rights. This right option will itself instantiate the rights-observing pattern in most imaginable cases but it will not do so in those exceptional circumstances where the best way to promote the pattern is not to instantiate it oneself: where the best way to promote rights observance is to breach those rights in one's own case.

Consequentialism, Global, and Local

Consistently with being a theory of the right, consequentialism can be thought of as having a smaller or a larger range of application to human agents (Pettit and Smith, 2000). There are sets of alternative acts that we might perform in different choices, sets of alternative decision procedures that we might follow in choosing acts, sets of alternative motives out of which we might be led to act, sets of alternative rules that we might comply with in acting, and so on. Is consequentialism a local

doctrine that just tells us what the best act is in any choice, for example – or the best decision procedure, or motive, or rule, or whatever – and that then says that the best alternatives in other sets are to be defined in a derived way? If acts are privileged, the best decision procedure might be that which produces the best acts, the best rule that which is consistent with the choice of the best acts, and so on through other categories. Or should consequentialism be taken to apply globally, telling us that as the best act is that which produces the best consequences among the alternatives on offer, so the same lesson holds for items in the other sets of alternatives?

Most consequentialist positions in the literature tend to be local in character. Act consequentialism, as it is called, tends to say that the best act is the act with the best consequences, and that the best factor in any other set of alternatives involving an agent is to be defined in some way – a number of ways are possible – by reference to how it serves the choice of best acts. Rule consequentialism gives the priority to rules in a parallel way, and motive consequentialism gives the priority to motives.

The most natural position, however, would seem to be global consequentialism (Parfit, 1984). It would say that no matter what the set of alternatives under consideration, the one to be preferred is that which does best by the consequences. The same lesson will apply, of course, to that set of alternatives whose members are different sets of act–procedure–motive–rule combinations; the right combination will be that which does best by the consequences overall. The act or procedure or motive or rule selected for any context under the best combination may not be the best possible one relative to the apparent alternatives in that context. But it will be the best possible one that is available consistently with the best possible combination overall.

The Role of Consequentialism

There is a long tradition among the opponents of consequentialist doctrines, in particular the opponents of utilitarianism, of suggesting that consequentialists are committed to holding that every choice should be made in a highly calculative, actuarial mode. F. H. Bradley made the point in the last century, writing about the utilitarian approach: "So far as my lights go, this is to make possible, to justify, and even to encourage, an incessant practical casuistry; and that, it need scarcely be added, is the death of morality" (Bradley, 1876, p. 107; see too Williams in Smart and Williams, 1973). Consequentialists have almost always resisted this charge. Thus, Henry Sidgwick in the last century and J. J. C. Smart in this have argued forcibly that utilitarianism does not require that agents all make their decisions by explicit reference to how the options will do by the promotion of happiness (Smart and Williams, 1973). The point they have wanted to make was nicely summed up early in the nineteenth century by the jurisprude, John Austin, in defending the utilitarian thinker: "he approves of love because it accords with his principle, he is far from maintaining that the general good ought to be the motive of the lover. It was never contended or conceived by a sound, orthodox utilitarian, that the lover should kiss his mistress with an eye to a common weal" (Austin, 1954, p. 108).

As recent consequentialists have almost all taken the view that consequentialism is a theory of the right, not a theory of the good, so they have nearly unanimously argued that it is a theory for assessing the right alternative for an agent or an agency to have adopted, not necessarily a useful theory to be applied in choosing from among alternatives. The point is usually made with respect to acts but it can also be extended to alternatives in other categories. The claim is that making one's decision by reference to which option has the best consequences may be a way of making one's decision that does not itself have the best consequences. Suppose one is concerned with one's own pleasure, for example. It is notorious that agents who make their decisions by reference to which option will promote the most pleasure may actually enjoy less pleasure than those who make their decisions in the more spontaneous fashion, say by reference to certain rules of thumb (Railton, 1984; Pettit and Brennan, 1986).

This aspect of consequentialism has been described as 'the paradox of teleology' (Scanlon, 1998, p. 383, n. 15). It has important implications and these need to be appreciated, if the appeal of consequentialism is to be understood. It means that the consequentialist can look with approval on agents whose mode of decision making in everyday life involves a consideration of consequences only in periodic reviews of their performance or in times of crisis. These agents may be routinely available to their family and friends; they may be reliable truth tellers and promise keepers; and they may be dependably respectful of the claims of others upon them. The consequentialist will approve of such people to the extent that they are more likely to promote the good – whatever view of the good is adopted – than actuarial, calculative types.

The Positive Case for Consequentialism

Why be a consequentialist? Surprisingly, there has been very little discussion of this question in the literature. Consequentialists tend to assume that if one is to be serious about the enterprise of moral assessment, then there is no alternative to looking at the consequences – the consequences, neutrally, or impersonally characterized – of the choices assessed. How could it be rational, they ask, to neglect any such consequences? They assume that if nonconsequentialists think otherwise, that is because of an unquestioning commitment to a theological or a commonsense viewpoint. A theological viewpoint might suggest that human agents ought to fulfill prescribed obligations and let God look after the consequences. And a commonsense viewpoint might support the attitude that the important thing in moral decision making is to look after one's own moral standing, to keep one's own hands clean, and not to worry, except perhaps in exceptional circumstances, about any bad consequences that may follow on this.

There is also a second reason why consequentialists may not have concerned themselves much with providing a defense of their position. Consequentialists are a mixed bunch, as we saw, insofar as they differ widely among themselves on the question of which substantive sorts of consequences – which valuable patterns – are the ones by reference to which choices ought to be assessed. For example, they divide into utilitarians and nonutilitarians, depending on whether or not they accept the

view that it is only consequences that bear on the utility of sentient beings which matter: only consequences that affect the happiness or preference satisfaction of such beings. Being a mixed bunch, consequentialists tend each to be concerned more with arguing for their particular view of what consequences count than with arguing for the shared consequentialist credo that it is indeed consequences that matter and not the sort of thing on which deontologists and other nonconsequentialists focus.

My own belief is that those who are attracted to consequentialism and nonconsequentialism are moved by different views of the nature of justification (Pettit in Baron et al., 1997). According to consequentialism, people will be able to think of their choices as justifiable to one another only insofar as they think that there are agent-neutral values that others ought to accept and that serve to justify those choices. According to nonconsequentialist positions, people will be able to think of their choices as justifiable under a weaker condition: if they think that there are agent-relative values such that others can be made to understand why they should be moved by those values – others are moved by corresponding values in their own case – and the values justify their choices. Thus consequentialists think that justification must ultimately be based on potentially shared or convergent concerns: say, with overall happiness or peace or good relations between people. But nonconsequentialists think that it can be based, even at the most ultimate level, on concerns that are isomorphic or concordant rather than convergent: say, on my concern that I should not break my promises, your concern that you should not break yours, whatever the impact on promise keeping more generally, or my concern with my children, your concern with yours, whatever the repercussions for overall child care.

The Negative Case for Consequentialism

But if consequentialists have not done much in the way of arguing for their position, what have been the issues debated between them and opponents (Scheffler, 1988; Darwall, 2003)? These have mainly had to do with how far consequentialism can support firm commonsense intuitions about what is morally right. Opponents typically object to consequentialism on the grounds that in one way or another it would undermine otherwise compelling moral attitudes. Rather than providing positive reason for adopting their position, consequentialists have often been content to try to deal with those objections or to try to argue that while the points made are valid, they are not as important as deontologists make them seem.

There are three sorts of objection, in particular, that consequentialists have had to confront in this exchange. First, and most traditionally, that their doctrine would make many intuitively wrong choices right, many intuitively right choices wrong. Second, an objection associated in particular with Bernard Williams (Smart and Williams, 1973), that even where it represents many intuitively right choices as right it would provide intuitively the wrong reasons for thinking them right. And third, a much debated objection, that it would represent as obligatory various right choices that are supererogatory, that is intuitively beyond the call of duty (Scheffler, 1982; Kagan, 1989; Murphy, 2000; Mulgan, 2001; Singer, 1993). Consequentialists have often argued in this exchange that our intuitions on relevant matters need to be revised but the more general line has been to maintain that on reflection consequentialism proves less counterintuitive than its opponents maintain.

The Collective Face of Consequentialism

Suppose we had a society of utilitarians, each of whom acted in a way that utilitarians would approve. Is it possible that the collective result of their so acting might be worse than the collective result of actions that did not individually earn utilitarian approval? Is it possible, in particular, that the collective result might be worse in utilitarian terms: that it might actually lead to less human happiness or preference satisfaction than certain alternatives? Is it possible that, however satisfactory as a theory of rightness for individual agents, it is not in this sense a collectively satisfactory theory (Hodgson, 1967)?

Does it matter that a theory designed for individuals is collectively self-defeating? Does it matter that agents who try to do what is best by the theory, or succeed in doing what is best by the theory, generate a collective result that is worse in their own terms than it might have been (Parfit, 1984)? Some are happy to say that a theory can be self-defeating in this way and yet remain a compelling theory for individuals. Others will think that this is a matter of the first importance for the assessment of a theory.

Some may be willing to concede that consequentialism can be collectively self-defeating but most deny this, on a variety of grounds (Lewis, 1972; Singer, 1972). One well-known line is that where collective self-defeat appears to threaten, it usually transpires that one of the options before the individuals is not being taken into account: say, the option of exploring possibilities of cooperation with others, rather than acting unilaterally, or the option of seeking further information on the prospects facing the agent (Regan, 1980).

Collective problems are actually more troublesome for nonconsequentialists. The prisoner's dilemma is often taken to show that what is individually rational may not be collectively rational: each of two prisoners confesses to a crime because, whatever the other does, confessing promises a better result than refusing to confess; yet each would be better off if both refused to confess than they are by both confessing. It is worth noting that where agents have distinct ends, as they will have under nonconsequentialism, then a prisoner's dilemma is a constant threat. The distinct ends that agents have may consist in individually wanting to do their own duty, individually wanting to instantiate the categorical imperative in their own behavior, individually wanting to do the best by their own children, and so on. Such ends are potentially competitive and so it is a permanent possibility that by each pursuing their own ends as best they can, they will secure a result under which neither does as well as they might have done in their own terms. By each trying to do the best they can by their own children, for example, they may each do less well than if they pooled their resources and did their best for children as such. Whatever problems are raised for consequentialism on the

collective front, it is better protected in this respect against prisoner's dilemmas, for it assigns to each agent the same end of promoting the best consequences (Parfit, 1984).

Some In-House Issues

There are a number of more or less in-house questions that are debated among consequentialists. One bears on how we should identify the alternatives to be evaluated in any decision. Should an agent do A or B, we ask. A, we answer, because its consequences do better on the relevant theory of the good. But what if there is some other option, C, which the agent might have chosen instead and which would have itself been better than A? This sort of example alerts us to the fact that in the consequentialist assessment of any choice, we have to be clear about what are the relevant alternatives to bring into consideration.

The question about alternatives has not received as much attention as it deserves in the literature, but it is undoubtedly of great importance (Bergstrom, 1966; Jackson and Pargetter, 1986). According to one view, we should assess any action against the alternative (or disjunction of alternatives) that the agent would have taken, had the action not been performed. According to another, we should assess it against the alternatives that the agent could have performed instead: against the alternatives that were, in a relevant sense, within the power of the agent. From a third-person point of view, the first approach would seem to be the most pertinent, although from a first-person point of view, things are not so clear.

A second in-house question has been more widely debated in consequentialist circles. This is the issue as to whether in looking at the decision an agent or agency ought to have made, we consider the actual consequences of the option chosen and the consequences that would have followed on alternatives; or whether, rather, we look at the expected consequences at the time of choice (Lewis, 1969; Jackson, 1991). If the answer is that we should look at expected rather than actual consequences, then the question is whether we should look at the subjectively expected consequences – in the manner of decision theory – or whether we should look at the consequences that were in some sense objectively expected (Menzies and Oddie, 1992). Suppose that a doctor prescribes a drug for a nonfatal skin condition, which has the following features: there is a 10 percent chance that it will kill the patient, an 80 percent chance that it will make no difference, and a 10 percent chance that it will cure the complaint. Imagine that the drug works and the complaint is cured. Does consequentialism take its cue from actual consequences and say that the doctor made the right choice? Or does it look to expected consequences, whether subjectively or objectively expected, and say that the doctor made the wrong choice? That is the issue here.

The third more or less in-house issue is whether consequentialism should hold that the right option is that which does best by relevant consequences – that which is optimific – or whether it is sufficient for an option to be right that it does well enough, as we might say, by the relevant consequences. Some theories of rationality are maximizing theories, requiring rational agents to maximize some function, whereas others are satisficing theories: these require rational agents just to perform satisfactorily by some relevant criterion. The question here is whether consequentialism should not take the softer, satisficing line rather than the stern, maximizing one (Slote and Pettit, 1984; Bradley, 2006).

Conservatism: Historical Aspects

JZ Muller, Catholic University of America, Washington, DC, USA

Abstract

Conservatism refers to an ideology and to the political movements in which this ideology plays a role. For reasons explained below, conservatism has been more difficult to define than other major modern ideologies. This article begins by exploring definitional difficulties, discusses approaches to the study of conservatism, offers a definition and characterization of conservatism as a distinct mode of political and social analysis, and finally provides a brief look at the history of the term and of the changing emphases of conservative thought.

Approaches to the Problem

An intuitive procedure for defining conservatism is to begin by listing the institutions that conservatives have sought to conserve. This will not get us very far, for conservatives have, at one time and place or another, defended a wide range of social, political, and economic institutions.

The study of conservatism has proved difficult for modern social science. Compared with the other great ideological phenomena of the past two centuries, such as liberalism, socialism, communism, or fascism, the subject of conservatism is underilluminated by scholarship. One reason is because of the difficulty of arriving at meaningful generalizations about conservatism, which displays less obvious uniformity across national borders and tends to be more nationally particular than liberalism or socialism, which aspire to be universal in their reach. Moreover, since conservatism emphasizes the need for institutional and symbolic continuity with the particular past, its symbols and institutional ideals tend to be more tied to specific, usually national, contexts. For all these reasons, studies of conservatism that go beyond one particular national context are scarce; as a result, conceptions of conservatism have tended to be parochial.

One of the earliest social scientific approaches to the issue was formulated by the Hungarian–German sociologist, Karl Mannheim, in his essay *Conservative Thought* (1927). He introduced the important distinction between traditionalism and conservatism, the former a near-universal psychological propensity to do things as they have traditionally been done and the latter an articulated set of interrelated political ideas, an ideology that arose, Mannheim thought, in response to the new and dynamic historical processes associated with the Enlightenment (*see* Enlightenment) and capitalist modernization (*see* Capitalism) and the bourgeois class (*see* Bourgeoisie and Middle Classes, History of). A pioneer of the sociology of knowledge, Mannheim claimed that conservative thought was linked to a worldview, which could be correlated with class position, roughly that of the feudal nobility. The basic categories of each ideology, he maintained, were unconsciously determined by the experience of the world and the self-interest of the class that developed it. In the case of conservatism, it led to a focus on experience and the concrete, as opposed to universalistic, rationalistic theories of liberalism and the Enlightenment. Conservatives offered a critique of the rationalistic conceptions for reorganizing society proposed by advocates of radical reform, and focused on explaining the historical particularities of real, existing societies and the interconnectedness of their institutions.

Subsequent social scientific analysts of conservatism, even when they have not followed Mannheim's focus on class, have stressed the reactive nature of conservatism, the fact that it arises in response to a challenge (intellectual, political, or cultural) to existing institutions, on behalf of which conservative arguments are then developed. In one of the most perceptive scholarly analyses of the subject, Samuel Huntington (1957) argued that conservatism is best understood not as an inherent theory in defense of particular classes and institutions, but as a positional ideology. "When the foundations of society are threatened, the conservative ideology reminds men of the necessity of some institutions and desirability of the existing ones," Huntington suggested. He claimed that because "the articulation of conservatism is a response to a specific social situation … . The manifestation of conservatism at any one time and place has little connection with its manifestation at any other time and place."

The reactive nature of conservatism is a premise of one of the finest historical studies of the subject, Klaus Epstein's *The Genesis of German Conservatism* (1966), which pays close attention to political and intellectual context and demonstrates how conservatism arose in German-speaking Europe as a response to the Enlightenment, commercial capitalism, and bourgeois liberalism. Taking the reactive approach a step further, Martin Greiffenhagen (1971), suggested that because self-conscious conservatism only arises once the institutions it values have lost their hold, conservative thought seeks not a preservation of the status quo, but uses an imaginatively transfigured conception of the past with which to criticize the present. According to Greiffenhagen, the romanticization of the past is thus an intrinsic and recurrent element of conservatism.

Two thinkers presented nonreactive conceptions of conservatism during the immediate postwar decade. In *The Conservative Mind* (1953), Russell Kirk, a US conservative man of letters, offered a conception of conservatism as based on religion and 'belief in a transcendent order, or body of natural law,

which rules society as well as conscience' – a conception that assimilated conservatism to religious orthodoxy, and was of scant use as an analytic tool. Kirk's conception was rejected by Michael Oakeshott, the most important British conservative philosopher of the era, in *On Being Conservative* (written 1956 and published in *Rationalism in Politics and Other Essays*, 1962), which presented a brilliant phenomenological description of conservatism as a disposition centered "upon a propensity … to delight in what is present rather than what was or what may be". Oakeshott sought to conserve a liberal and pluralist conception of society, and doubted that 'a disposition to be conservative in politics' depended on the religious and metaphysical assumptions set forth by Kirk.

Definition and Characterization

To understand conservatism as a distinctive mode of social and political thought, it is useful to distinguish it, ideally typically at least, from reaction and orthodox. The orthodox theoretician defends existing institutions and practices because they are metaphysically true: the truth proclaimed may be based on particular revelation or on natural laws purportedly accessible to all rational men; it may be religious or secular in origin. The conservative defends existing institutions because their very existence creates a presumption that they have served some useful function; because eliminating them may lead to harmful, unintended consequences; or because the veneration that attaches to institutions that have existed over time makes them potentially usable for new purposes.

Conservatism can similarly be distinguished from reaction. The conservative seeks to conserve existing institutions, usually recognizing that the process of conservation may include the need for evolutionary reform. The reactionary, by contrast, is at odds with existing institutions, and seeks to return to some institutional status quo ante, often in a form transfigured by memory and ideology.

As misleading as the confusion between conservatism and orthodoxy is the false dichotomy of conservatism and the Enlightenment. Contrary to the frequent characterization of conservatism as the enemy of the Enlightenment, it is more historically accurate to say that there were many currents within the Enlightenment, and some of them were conservative. Indeed, conservatism as a distinct mode of thought is a product of the Enlightenment. What makes social and political arguments conservative as opposed to orthodox is that the critique of liberal or progressive arguments takes place on the enlightened grounds of the search for human happiness, based on the use of reason.

Characteristics of Conservative Thought

Conservative theorists repeatedly decry the application to society and politics of a mode of thought that they characterize as overly abstract, rationalistic, and cut off from experience. Whether termed 'the abuse of reason' (by Burke 1790), 'rationalism in politics' (by Oakeshott, 1962) or 'constructivism' (by Hayek), the recurrent conservative accusation against liberal and radical thought is that they are said to depend on a systematic, deductivist, universalistic form of reasoning that fails to account for the complexity and peculiarity of the actual institutions that they seek to transform.

For conservatives, the historical survival of an institution or practice – be it marriage, monarchy, or the market – creates a prima facie case that it has served some human need. The conservative emphasis on 'experience' is linked to the assumption that the historical survival of an institution or practice is evidence of its fitness in serving human needs. Since custom and habit are important features of human conduct, some of the usefulness of a practice comes from the fact that those engaged in it are already 'used' to it, and are apt to be discomfited by change.

Conservative thought has typically emphasized the imperfection of the individual, an imperfection at once biological, emotional, and cognitive. Conservatives typically contend that human moral imperfection leads men to act badly when they act upon their uncontrolled impulses, and that they require the restraints and constraints imposed by institutions as a limit on subjective impulse. Conservatives, thus, are skeptical of attempts at 'liberation.' Conservatives have also stressed the cognitive element of human imperfection, insisting on the limits of human knowledge, especially of the social and political world. They warn that society is too complex to lend itself to theoretical simplification, and that this fact must temper all plans for institutional innovation.

These assumptions explain the emphasis of conservative social and political thought on institutions, that is, patterned social formations with their own rules, norms, rewards, and sanctions. While liberals typically view with suspicion the restraints and penalties imposed on the individual by institutions, conservatives are disposed to protect the authority and legitimacy of existing institutions because they believe human society cannot flourish without them. Unlike liberals, who favor voluntary, contractual social relations, conservatives emphasize the ongoing importance of nonvoluntary duties, obligations, and allegiances.

Although there is no necessary link between conservatism and religious belief, conservatives have tended to affirm the social utility of religion. They make several arguments for the utility of religion: that it legitimates the state; that the hope of future reward offers men solace for the trials of their earthly existence and thus helps to diffuse current discontent, which might disrupt the social order; and that belief in ultimate reward and punishment leads men to act morally by giving them an incentive to do so.

Conservatives typically emphasize the unanticipated negative consequences of deliberate social action. Such negative consequences, they argue, occur because reformers are unaware of the latent functions of existing practices and institutions. Reformers are insufficiently cognizant, it is said, of the contribution of the practice to the preservation or adaptation of the larger social system in which it is implicated. That contribution may be unintended by those engaged in the practice, so that its function may be unrecognized, or recognized only retrospectively, once the reform of the practice has brought about negative unintended consequences.

Together, the concepts of unanticipated negative consequences, latent functions, and functional interdependence

serve as recurrent arguments against radical or wholesale reform, although not against reform as such.

Recurrent substantive themes of conservative social and political thought include:

1. a skepticism regarding the efficacy of written constitutions, as opposed to the informal, subpolitical, and inherited norms and mores of society; for conservatives, the real 'constitution' of society lies in its historical institutions and practices, which are inculcated primarily through custom and habit;
2. the central role of cultural manners and mores in shaping character and restraining the passions, and hence the political importance of the social institutions in which such manners and mores are conveyed;
3. an emphasis on the family as the most important institution of socialization, and despite considerable divergence among conservatives over the proper roles of men and women within the family, the assertion that some degree of sexual division of labor is both inevitable and desirable;
4. the legitimacy of inequality, and the need for elites, cultural, political, and economic; security of possession of property as a prime function of the political order; and
5. the importance of the state as the ultimate guarantor of property and the rule of law, and hence the need to maintain political authority.

Historical Overview

Terms related to 'conservative' first found their way into political discourse in the title of a French weekly journal, *Le Conservateur* founded in 1818 by François-René de Chateaubriand with the aid of Louis de Bonald. "The *Conservateur* upholds religion, the King, liberty, the Charter and respectable people (*les honnêtes gens*)," it proclaimed in its first issue. In England, the label 'Conservative Party' was first applied to the Tories by the publicist John Wilson Crocker in 1830. In Germany, the term 'conservative' came into use later in the same decade: it was first employed as an epithet against those designated as conservative, who were accused of seeking to preserve existing institutions at any price, but the term was eventually accepted by those it had been used to stigmatize. But as with many other historical developments, the phenomenon of conservatism long preceded the use of the term in political life.

The precursors of conservatism may be found in the Anglican critique of the Puritan contention that the elect or the inspired congregation, guided by their individual interpretations of the Bible, were entitled to exercise political authority. The thought of David Hume marks a watershed in the development of conservative social and political thought into a coherent, secular doctrine. Hume began by borrowing and expanding upon this critique of the politics of religious 'enthusiasm.' And he went on to criticize what he saw as its secular counterparts in the philosophically implausible and politically subversive doctrines of natural rights and of voluntary contract as the sole legitimate basis of political obligation. In 1757, Edmund Burke used similar terms to attack what he called the 'abuse of reason' among some enlightened thinkers. On the Continent, conservative social and political thought arose as a critique of the policies of enlightened absolutism. Among the foremost practitioners of this criticism was Justus Möser, himself a part of the German Enlightenment, and a reformer of a conservative and corporatist tinge. In Holland, another Enlightenment figure, Jean de Luzac, articulated politically conservative arguments opposing the claims of 'patriots' for a more democratic constitution. The contention that conservatism arose in opposition to the Enlightenment and to the French Revolution reflects Edmund Burke's polemical characterization of the Enlightenment in his critique of the French Revolution. Although frequently reiterated, the contention is historically untenable. Conservatism arose not against the Enlightenment but within it. Much of post-1789 intellectual conservatism is continuous with the analytic strategies, if not with the tone, of prerevolutionary conservative analysis.

It was the democratic radicalism of the French Revolution that evoked Burke's *Reflections on the Revolution in France* (1790), which became the most influential work in the history of conservative thought. Joseph de Maistre (1753–1821) and Louis Gabriel de Bonald (1754–1840) were the two leading figures in the tradition of French counterrevolutionary thought. The task with which they saw themselves confronted was rather different than the one that had motivated Burke's *Reflections*, and the nature of their conservatism varied accordingly. Burke's primary task was to conserve a British order that was substantially intact, although subject to intellectual attack. He could thus stress the historical utilitarian arguments that the existence of an institution creates a prima facie case that it has served some human need, and that historical continuity is intrinsically valuable because it increases the emotional hold of an institution on its members. Similarly, Burke could underscore the importance of habit and custom. By the time de Bonald and de Maistre came to write their major works, the forces of the French Revolution had already overturned or transformed many of the key institutions of the Old Regime. The counterrevolutionary conservatives, therefore, were forced by circumstances to offer a rationale other than that of historical continuity, for the institutions of the old regime had been disrupted by the Revolution. de Maistre responded to the revolution by carrying to new lengths previous conservative arguments of epistemological modesty, historical particularism, and the unanticipated consequences of deliberate action.

Burke's defense of monarchy, aristocracy, and the established church stamped European conservative thought at the end of the eighteenth century and in the early decades of the nineteenth century. Yet a similar critique of democratic radicalism appears, with a more republican but, nevertheless, recognizably conservative thrust, in the United States, first in the writings of the US Federalists, and later in the work of conservative Whig critics of Jacksonianism, such as Rufus Choate. Hume's combination of political conservatism with the championing of commerce was to remain characteristic of subsequent British and US conservatism. By contrast, the French, Catholic strains of conservatism of de Bonald and de Maistre, as well as the romantic German strains of conservatism remained less accepting of capitalist economic development than the British and US strains.

The development of conservative social and political thought after the mid-nineteenth century shows a movement from substance to function: from the defense of particular institutions to the defense of institutions in general, from the defense of the landed aristocracy to a defense of elites in general, from an emphasis on the role of the established Church to the function of culture in linking the individual to communal purposes, and from monarchical authority to the authority of the state in general. In the last decades of the nineteenth century, conservatism underwent an important shift, reflecting a change in opponents and in institutional substance. The increasing dominance of industrial capitalism, the expansion of the suffrage, the rise of socialist movements, and the rise of a new brand of liberalism that was more economically redistributionist and more culturally permissive, all led to a substantial transformation of conservatism. Many of the economic institutions and policies once associated with European liberalism (*see* Liberalism: Political Doctrine and Impact on Social Science) now became that which conservatives sought to conserve. This new brand of conservatism was pioneered in late nineteenth-century Britain, and is reflected in the works of James Fitzjames Stephen and W.H. Mallock and by the US theorist, William Graham Sumner.

The rhetoric by means of which institutions were defended also changed. It placed less emphasis on the veneration of tradition as such, while seeking to increase the emotional hold of existing institutions by showing that they were in accord with the needs of historical development. In England and the United States, the language of common law and of inherited tradition was increasingly abandoned in favor of the language of science. The justification of the social utility of landed elites was replaced by a more general defense of the need for elites in the realms of economics and politics, while the defense of the established Church was transformed into a defense of cultural elites. In Germany, too, the substance of conservatism was transformed, from a defense of aristocracy, a social order based on fixed estates, and paternalist monarchism, toward an emphasis on the functions of the state as such, a transformation exemplified in the work of the twentieth-century German theorist, Carl Schmitt.

One recurrent strand of thought that is related to conservatism, yet politically and analytically distinct from it, is radical conservatism, a strand particularly powerful in interwar Europe, where its adherents often came to favor fascist regimes (*see* National Socialism and Fascism). Radical conservatives share some of the concerns of more conventional conservatism, such as the need for institutional authority and continuity with the past. But they maintain that the processes characteristic of modernity have destroyed the valuable legacy of the past for the present, so that a restoration of the purported virtues of the past demands radical or revolutionary action. Hence the credo of one radical conservative, Moeller van den Bruck, that 'Conservative means creating things that are worth conserving.' Radical conservatism shares with conservatism an emphasis on the role of institutions in providing restraint and direction to the individual, but seeks to create new institutions that will exert a far stronger hold on the individual than do existing ones, which because of their relative tolerance are perceived by radical conservatives as 'decayed.'

After the defeat and discrediting of fascism, conservatism in the later half of the twentieth century was defined not only by its opposition to communism but also by antipathy to the spread of the welfare state and attempts to bring about economic redistribution, and by skepticism regarding the solution of social problems through massive governmental action.

The study of conservative movements and conservative ideology provide an ongoing challenge to social scientists. For they must provide analyses of a phenomenon that is dynamic and changes over time, that varies between nations and often between regions within nations, and that often appears in combination with a variety of other trends (religious, nationalist) and under a variety of nomenclatures. These difficulties – together with the political predilections of the majority of social scientists, who tend to be antipathetic to conservatism – have led to a gap between the historical significance of conservatism and the extent of its exploration by scholars. This is lamentable, for more-or-less conservative parties have dominated western European and US politics for substantial portions of the past two centuries, and conservative thinkers have played a leading role in the development of modern thought.

Abstract

The origins and development of conservatism as political theory and political ideology are reviewed. While self-consciously conservative political parties could be found in England as early as 1832, a self-consciously conservative movement in the United States only emerged in the 1950s. A common hostility to Communism and the Soviet Union linked the advocates of religious and moral traditionalism with defenders of free enterprise and opponents of big government. Today, conservatism is identified mainly with resistance to change.

Edmund Burke, writing in his *Reflections on the Revolution in France* (1790) first expressed the basic principles of conservatism; he argued for authority and tradition over revolutionary transformation, for hierarchy and deference over equality, for the community over the individual, local control over state centralism, and religious and moral values as opposed to relativism and anticlericalism. His views were taken up by the British Tory Party when it renamed itself the Conservative Party following the 1832 Reform Act and were echoed by similar parties elsewhere in Europe. A self-consciously conservative movement in the United States only emerged in the 1950s. A common hostility to Communism and the Soviet Union linked the advocates of religious and moral traditionalism with defenders of free enterprise, and opponents of big government. They were joined in the 1970s by the neoconservatives, a group of ex-liberal intellectuals who opposed the radicalism of the 1960s and the anti-Americanism of some of the opponents of the Vietnam War. The Religious Right, reacting to Supreme Court decisions outlawing school prayer and upholding a constitutional right to abortion provided a broader populist basis for the movement. Under the leadership of Ronald Reagan conservatives won the presidency in 1980 and proceeded to enact their agenda in domestic and foreign policy. The end of the Cold War led to increasing tension between social conservatives who called for increased support for religious and moral values and economic conservatives who favored free enterprise, local control, and a diminished role for the federal government. However, the continuing human ambivalence about the pace and nature of change ensure that the liberal–conservative debate will continue for the foreseeable future.

Definition

An initial problem that arises in attempting to define conservatism is whether it is a theory or simply an attitude towards change. Most dictionary definitions incline toward the attitudinal definition, describing conservatism as a preference for existing institutions, and opposition to change. With this definition the content of conservatism will vary depending on whatever is the current institutional and ideological status quo. Yet the writers, parties, and movements that have described themselves as conservative share a number of common values and doctrines, which typically include theories of human nature, history, society, and politics.

The term 'conservatism' was first used in England after the 1833 Reform Act when the Tory Party, which had roots going back to the late seventeenth century, renamed itself the Conservative Party. The central doctrines of conservatism were expressed before the word was invented, most notably in Edmund Burke's *Reflections on the Revolution in France* (1790), where we can find most of the central doctrines of conservatism, developed in response to the liberal and radical thinking of the French revolutionaries. In opposition to their demand for liberty, Burke stressed the values of order, tradition, and gradual change. Against the revolutionaries' call for equality, Burke stressed society's need for hierarchy, deference, class differentials, and a special position for the church and the nobility. In opposition to the radical individualism of the French, he insisted on the importance of community, tradition, and history. He criticized the anti-institutional rationalism of the revolutionaries by stressing the importance of social institutions that have stood the test of time, and the weakness and fallibility of individual reason. Against their centralizing statism, he lauded the 'little platoons' of localism as defenders of liberty, and contrary to their anticlericalism, he praised the elevating effect of inherited religious beliefs.

In developing these ideas Burke was able to draw on the Western tradition, classical ideas of natural law, Christian views of hierarchy and man's inherited inclination to evil, as well as medieval practices of localism and organic corporate groups. Although himself an adherent of the Whig Party, his ideas were influential not only on the thinking of the British Conservative Party, but on conservative parties and movements elsewhere in Europe, and later in the United States. As originally expressed, their emphasis on order over freedom, hierarchy over equality, religion over anticlericalism, localism over centralism, and community over the individual stood in marked contrast to the liberal doctrines that they criticized.

European Conservatism

In the political struggles of nineteenth and twentieth centuries, European conservative parties drew on the conservative

tradition to defend the interests of property, the upper classes, the military, and the church, and appealed to nationalist and patriotic feelings in support of their programs. Their efforts were not restricted to the defense of class and privilege. In 1867, hoping to secure lower class support for 'tory democracy,' Benjamin Disraeli, the Conservative Prime Minister in England, extended the suffrage. Otto von Bismarck initiated a program of social insurance in Germany to counteract socialist appeals; and Pope Leo XIII in his 1891 encyclical, *Rerum Novarum*, defended the living wage for the worker, and promoted the organization of trade unions (preferably under church auspices) while denouncing the extremes of liberalism and socialism. Less laudably, conservative parties in Germany, Austria, and elsewhere, in the twentieth century, sometimes allied themselves with or supported extreme rightists and even fascists and Nazis, seeing them as a bulwark against Communism. Hitler, for example, was able to come to power legally because of the votes of German conservatives.

The conservative impulse continues to be important in European politics. Since the 1833 Reform Act the British Conservative Party has been in power much longer than any other party. On the continent Christian Democratic centrist parties often work together with conservative groupings, linked by their commitment to religion, and to a 'social market economy.' Twentieth-century conservatives, despite earlier hostility to market forces, have increasingly embraced free enterprise economics. They have been critical of European economic and political integration on nationalist grounds. Nationalist resistance to foreign immigration also accounts for some of the support for conservative parties and movements.

Conservatism in America

In *The Liberal Tradition in America*, published in 1955, Louis Hartz argued that with the exception of a few Southerners, notably John C. Calhoun, Americans were all Lockean liberals, and that European-style conservatism was absent from the American political scene (Hartz, 1955). Ironically at the very time that his book was published, a genuine and self-conscious conservative movement had begun to emerge on the American scene. Russell Kirk had published *The Conservative Mind* (Kirk, 1953) arguing that Burke rather than Locke should be the model for America. At the University of Chicago, the German émigré political theorist, Leo Strauss, published *Natural Right and History* (Strauss, 1953), which attacked Locke as a proto-Hobbesian and denigrated the natural-rights tradition in favor of classical models of politics, especially that of Plato. Another émigré, Erich Voegelin, appeared on the cover of *Time* magazine after he published *The New Science of Politics* – in which he associated communism, liberalism, and revolutionism with a Christian heresy, gnosticism, that attempted to establish heaven on earth (Voegelin, 1952). Whittaker Chambers, who had accused Alger Hiss of spying for the Soviet Union, also linked Communism and liberal utopianism in his book, *Witness* (Chambers, 1952). In 1955 William Buckley, the *enfant terrible* who had earlier published *God and Man at Yale*, an attack on the dominance of secular and leftist views at his *alma mater*, founded *The National Review* as a journal to promote conservative political and economic thought. Combining militant anti-Communism, the defense of traditional values, and the promotion of free enterprise economics, it became the principal organ of the conservative movement in America.

Together these publications formed the intellectual basis of the conservative movement in mid-twentieth-century America. As in the case of William Buckley, their conservatism was also linked to free-enterprise economics, as defended in the writings of two University of Chicago economists, Friedrich Hayek and Milton Friedman. In *The Road to Serfdom* (Hayek, 1944) and later works, Hayek argued that the growth of government threatened liberty and stifled the economy, while Friedman's 1955 lectures, published as *Capitalism and Freedom* (Friedman, 1962) developed similar themes, as well as making innovative proposals to increase competition and privatize government functions, many of which were adopted in later decades. Their arguments were based on classical economic liberalism, but in the American context the two economists were viewed as conservative since they defended the existing capitalist system. In addition, their common hostility to Communism linked them to the social and political conservatives in the newly burgeoning movement.

The conservative movement became a major factor in national politics with the presidential candidacy of Barry Goldwater in 1964. After Goldwater's defeat, Ronald Reagan became the movement's leader. Promising to revitalize national defense against the Soviet Union, restore moral values, and downsize the welfare state and reduce the scope of the federal government, he led the conservative wing of the Republican party to victory in the presidential election of 1980. In the late 1970s, the conservative movement received support from a new group, the Neo-Conservatives, former liberal intellectuals who criticized what they perceived to be liberal weakness in the face of the Communist threat, and rejected the excesses of the New Left counterculture that had emerged in the 1960s (Kristol, 1983). They provided key policy makers to the Reagan administration in the areas of defense and education, while the free market economists directed economic policy, cutting taxes and welfare programs.

The Religious Right

Conservatism in America had often been an elite phenomenon, but the Religious Right gave it a broader populist base. Building on the religious opposition to the Supreme Court decisions outlawing school prayer and recognizing a constitutional right to abortion, conservative churchmen, mostly but not exclusively evangelical Protestants, organized the Moral Majority, and later the Christian Coalition, to reverse what they saw as a liberal tendency to secularism and toleration of immorality. They also shared with other conservatives opposition to the Soviet Union, and a belief in free market economics. In the 1990s, they opposed the gay rights movements, and the increasing toleration of homosexuality in America. They became an important pressure group within the Republican Party, effectively vetoing candidates for national office who favored abortion, and pressing for the appointment of Supreme Court justices who were sympathetic to their views.

Tensions within Conservatism

American conservatism contains within it many different currents. Ronald Reagan and the Soviet threat could hold its various strands together, but with the end of the Cold War there were increasing tensions among them, in particular as to whether social and moral issues, or downsizing government and encouraging free markets, should be given priority in public policy. Concern about moral decline, a frequent conservative theme (Bennett, 1993) and issues such as abortion, gay rights, and public prayer became the subject of *Culture Wars* (Hunter, 1991) from local school districts to the Supreme Court.

The members of the Supreme Court, most of them appointed by Republican presidents, became deeply divided along conservative–liberal lines, both as to theories of constitutional interpretation – 'original position' versus 'the living constitution,' federal-state relations – and as to the rights of the individual against those of society. Decisions by a 5–4 majority were frequent, and the question of the ideological sympathies of future Supreme Court appointees was an issue in the 2000 presidential campaign.

The Future of Conservatism

A line in a Gilbert and Sullivan operetta asserts that 'every little boy and girl alive, is either a liberal or a conservative.' It seems that conservatism, in the sense of a reluctance to make rapid and wholesale change, is related to a continuing need in the human psyche. It also expresses a general set of preferences about politics and society that undergirds the ideology and program of many political parties and movements. While there may be a broad ideological consensus on the values of democracy and market economics, there will continue to be debate about the relation of the individual to society, the respective demands of freedom and order, the extent to which equality is necessary or desirable, the proper allocation of roles to state and non-state actors, and the need for mediating institutions and local self-government. As long as this is the case, a future role for conservativism as a theory and ideology seems assured.

Editor's Note

American conservatism did not die with Ronald Reagan, of course. For an update on American conservatism since the publication of Sigmund's entry, see Charles W. Dunn, 2014.

Consociationalism

Rudy B Andeweg, Leiden University, Leiden, The Netherlands

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Consociationalism or consociational democracy means that the destabilizing effects of deep social cleavages can be offset by cooperation between subcultures at the elite level. Consociationalism is characterized by grand coalition, segmental autonomy, proportionality, and minority veto. Consociational theory sometimes is equated with the publications of its most influential scholar, Arend Lijphart. The theory is used empirically to explain stable democracy in deeply divided societies (e.g., the Netherlands, Lebanon) and normatively to prescribe a solution when democracy is at risk because of social segmentation (e.g., Northern Ireland, South Africa). The theory sometimes is criticized for its classification of particular countries, the operationalization of its key concepts, and the identification of factors that are favorable to the emergence of consociationalism. A recent offshoot of consociationalism is consensus democracy, which is defined institutionally rather than behaviorally, and also applies to countries without deep social cleavages.

The term 'consociational' dates back at least to 1603, when the German scholar and statesman Althusius used it to denote a polity consisting of an association of several societies. In modern political science, "Consociational democracy means government by elite cartel to turn a democracy with a fragmented political culture into a stable democracy" (Lijphart, 1969: p. 216). Although this situation has been labeled in a variety of ways ('Politics of Accommodation,' 'Power-sharing,' '*Pacificatie-democratie*' (in Dutch), '*Proporzdemokratie*' or '*Konkordanzdemokratie*' (in German)), consociational democracy (or consociationalism) is the term that is most widely used. Consociationalism is used empirically to explain stable democracy in deeply divided societies and normatively to prescribe a solution to societies where democracy is at risk because of subcultural conflict.

The Consociational Explanation

Deep social cleavages, whether they are based on ideology, religion, class, language, or ethnicity, generally are regarded as unfavorable conditions for stable democracy. The risk is limited when cleavages are crosscutting (e.g., when members of a particular ethnic group belong to different social classes), because this is supposed to generate cross pressures which have a moderating effect on social conflicts. The risk is greatest when social cleavages coincide and reinforce each other (e.g., when all members of a particular ethnic group belong to one social class, and all members of another ethnic group to another). However, there are democracies that maintain political stability despite coinciding cleavages. In the late 1960s and early 1970s, case studies of several such countries revealed a common pattern: social conflict was not moderated by crosscutting cleavages at the mass level, but by cooperation between the social segments at the elite level (e.g., Lehmbruch, 1974; Lijphart, 1975; Steiner, 1974).

By looking at both the mass level and the elite level, a fourfold typology of democratic regimes was developed, as shown in Figure 1. The situation of a homogeneous society and competing elites is most conducive to stable democracy. The United States and the United Kingdom serve as examples of such 'centripetal democracy.' One might argue that the combination of social homogeneity and elite cooperation guarantees stability even more, but the lack of democratic choice in such a 'depoliticized democracy' is likely to lead to antisystem opposition. The situation that is most dangerous for stable democracy is where society is divided deeply and the leaders of the social segments compete. Classic examples of this 'centrifugal democracy' are Weimar Germany and the French Fourth Republic. Consociational democracy represents the situation in which deep social divisions are prevented from destabilizing democracy by elite cooperation.

The list of countries that are claimed to be or to have been consociational democracies gradually has expanded and, without claiming to be complete, now includes Austria (1945–66), Belgium (from 1918), Bosnia-Herzegovina (since 1995), Burundi (since 2005), Canada (1840–67), Colombia (1958–74), Cyprus (1960 and 1963), Czechoslovakia (1989–1993), India (1947 to the late 1960s), Lebanon (1943–75 and after 1989), Luxembourg, Malaysia (1955–1969 and since 1971), Macedonia (since 2000), the Netherlands (1917–67), Northern Ireland (after 1998), South Africa (1993–96), and Switzerland (since 1943), with contemporary Canada and Israel being classified as semiconsociational. The extent to which the political system of the European Union can be described as consociational is debated (e.g., Bogaards and Crepaz, 2002). As can be seen from the dates, consociationalism has disappeared in some cases, either because it failed (sometimes because of international interference: Lebanon, Cyprus) or because it was so successful in accommodating the social cleavages that it rendered

		Structure of society	
		Homogeneous	Plural
Elite behavior	Coalescent	Depoliticized democracy	Consociational democracy
	Adversarial	Centripetal democracy	Centrifugal democracy

Figure 1 Lijphart's typology of democratic regimes. Reproduced with permission of Yale University Press from Lijphart, A., 1977. Democracy in Plural Societies: A Comparative Explanation, p. 106, Figure 2.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93025-3

itself superfluous (e.g., in Austria and the Netherlands). Because of the latter cases, consociationalism is sometimes seen as a transitional phase.

Although there have been deductive approaches to consociationalism (e.g., Nordlinger, 1972), the theory of consociational democracy has been developed primarily by generalizing from case studies (e.g., Lijphart, 1977; Taylor, 2009). Lijphart's contribution has been so influential that consociationalism often is equated with his work. He distinguishes four characteristics, each of which should be present for a country to be classified as consociational: (1) government by grand coalition (i.e., including representatives of all social segments); (2) segmental autonomy (federal arrangements in case of geographical concentration of subcultures (*see* Federalism), or subcultural autonomy with regard to schools, etc.); (3) proportionality in the electoral system (*see* Proportional Representation), but also with regard to civil service appointments, distribution of public funds for schools, etc.; and (4) minority veto (sometimes in the form of qualified majority requirements for certain types of legislation).

In a later offshoot of consociationalism, Lijphart elaborated a distinction between majoritarian democracy, which is characterized by 10 institutional features that concentrate power in the hands of the majority, and consensus democracy, which is characterized by an identical number of features that make decision making as inclusive of all relevant parties or groups as possible (Lijphart, 2012). Although the characteristics of consociational democracy are primarily behavioral whereas the characteristics of consensus democracy are largely institutional, and although consociationalism is also defined by the existence of deep social cleavages, both concepts clearly overlap and many consociational democracies are also classified as consensus democracies.

The Consociational Prescription

Consociational engineering is recommended as the only viable option for deeply divided countries that seek to achieve or maintain stable democracy. Two prominent cases in which this advice appears to have been influential are Northern Ireland and South Africa. The 1998 Good Friday Agreement in Northern Ireland, which was endorsed by referendums in Northern Ireland and in the Irish Republic, contains several clearly consociational characteristics (dual premiership, a proportional electoral system (STV), requirements for 'parallel consent' in the legislature, etc.). In South Africa, the transition from apartheid was facilitated by a consociational interim constitution (including a government of national unity and an electoral system of proportional representation), but in the constitution of 1996 few consociational elements remain.

The prescriptive use of consociationalism has sparked a debate on the conditions that are favorable and unfavorable to the successful adoption of a consociational solution (e.g., Andeweg, 2000; O'Leary, 2005). It is more likely that elites refrain from intersegmental competition if they perceive the benefits of competition to be outweighed by its costs. This is the case when no social segment has a majority or can entertain any hope of achieving a majority. However, even if one segment has a (near) majority, its leaders may still prefer to share power with the minority if that minority has inflicted casualties or economic damage on the majority or can credibly threaten to do so, or if the minority's support is indispensable to face an external threat. In addition, it is more likely that a consociational solution succeeds when followers agree with their leaders' choice of intersegmental cooperation, or when the elites are relatively immune from intrasegmental competition. The latter is the case when elites control the mass media, or when dense networks of subcultural organizations or patron–client networks make it difficult for competitors to challenge the incumbent elites.

Some other factors that are mentioned as favorable to the emergence of consociationalism are less self-evident (social segments of equal size, a small country, geographical concentration of segments, etc.). An important remaining question is whether some social cleavages are more amenable to elite accommodation than others. In view of consociationalism's potential for deeply divided countries, the question whether ethnic (as opposed to religious or class) cleavages constitute a favorable or an unfavorable condition is of particular relevance. Another open question is the extent to which consociational arrangements can be imposed successfully by outside actors (other countries, international organizations). Cases of coercive consociationalism, or at least outside involvement, include Northern Ireland, Macedonia, Bosnia-Herzegovina, and Burundi, but there are also examples of failure (Cyprus, Iraq).

Critiques of Consociationalism

The central tenet of consociationalism (i.e., that political stability need not be safeguarded by cross-cutting cleavages at the mass level, but can also be maintained by intersegmental elite cooperation) has gone relatively unchallenged. In addition to controversy over favorable and unfavorable factors, most of the criticisms that have been passed on consociationalism as an explanatory theory are directed at the classification of some countries as consociational democracies, and at the way in which key concepts have been defined and operationalized, in particular by Lijphart (e.g., Barry, 1975; Lustick, 1997). The country whose consociational credentials have been called into question most is Switzerland. The debate centers on the question whether Swiss society is deeply divided, as religious and class cleavages cross-cut linguistic divisions, and as the linguistic segments had very few ambitions that brought them into conflict with one another.

Such controversies, it is argued, arise from the vagueness and elasticity with which many of the key concepts of consociationalism such as segmentation are defined (Halpern, 1986). For example, one of consociationalism's four characteristics, grand coalition, includes not only all-party governments (as in Switzerland), but also oversized coalitions, all-party advisory commissions, 'diachronic coalitions' in which power rotates, as in Colombia between 1958 and 1974, or joining forces in a single 'consociational party' (Bogaards, 2014). These different mechanisms can still be seen as functional equivalents that all facilitate elite cooperation, however. A more important problem is that elites are unlikely to cooperate all the time, on all issues, and in

all arenas. Even in consociational democracies, elites tend to compete in elections, for example. Any classification of elite behavior as adversarial or coalescent therefore must rest on an often-impressionistic aggregation of elite behavior across issues and arenas.

The consociational prescription has also come under attack (see O'Leary, 2005), in particular with regard to the treatment of social cleavages. Consociationalism sees social cleavages as given obstacles to social peace, not as social constructs that might be changed (Dixon, 2012). Consociational engineering may even reinforce subcultural identities (Horowitz, 1985) and provide an incentive to incite subcultural conflict in order to obtain further concessions (Tull and Mehler, 2005). In response, a 'liberal consociationalism' that allows social identities to change is now distinguished from the original 'corporate consociationalism' (McCullogh, 2014). Another concern over the prescriptive use of consociationalism regards its democratic credentials. The democratic quality of consociationalism is sometimes impugned because of the predominance of elites and the absence of opposition. From the perspective of democracy as a device to keep elites accountable and responsive to the masses, this is a pertinent criticism. However, in the deeply divided societies for which consociationalism offers a solution, the most salient distinction is not between elites and masses, but between social segments of a more or less ascriptive nature. In that situation, democracy may be better served with a relative emphasis on inclusiveness, and in that respect consociational democracy (and consensus democracy) outperforms adversarial or majoritarian democracy.

Conspicuous consumption and distinction, history of

Connor J Fitzmaurice, Boston University, Boston, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept of 'conspicuous consumption' is the idea that consumers make explicit comparisons to others when consuming in an effort to portray actual and aspirational statuses. The concept of 'distinction' reduces the emphasis on explicit comparisons; consumer choices are seen as predicated on taken-for-granted, internalized norms of appropriate taste. These taken-for-granted ways of perceiving the world and consuming are means of marking the social boundaries of class. While status models of consumption were once dominant in the social sciences, these concepts have undergone considerable critique, particularly when applied outside the contexts in which they were initially developed.

Attention to the concepts of conspicuous consumption and distinction has played a critical role in understanding consumer behavior within the social sciences. However, the application of these concepts has not been uncontested. Of central concern is how taste shapes consumption, and the extent to which status-seeking behavior may or may not shape consumer preferences. Nevertheless, over the course of their intellectual history, these concepts – and their critiques – have provided analytic power for social scientists studying issues of consumption, status, and taste.

The role of taste in consumption has long been problematic for social scientists. For example, the models of mainstream economics rely upon the assumption of independent, fixed tastes or preferences. As George Stigler and Gary Becker explain, once a situation arises in which tastes appear not to meet these criteria of stability and independence, and ascertaining the underlying origins of taste becomes paramount, traditional economic inquiry is abandoned: for traditional economics, differences in taste are incontestable (1977). However, analytic insight is gained by paying attention to those situations in which consumer tastes change and, rather than operating independently, seem to be shaped by consumers' social positions and status-seeking behaviors. It is in such cases that social scientists have effectively appealed to the concepts of conspicuous consumption and distinction.

From Conspicuous Consumption to Distinction

The concept of 'conspicuous consumption' is the idea that consumers make explicit comparisons to others when consuming goods, services, and leisure in an effort to portray actual and aspirational statuses. Specifically, consumers are conceptualized as attempting to emulate the purchasing decisions of those above them on the status hierarchy or, at the very least, as attempting to defensively keep up with similar others. Developed later, the concept of 'distinction' reduces the emphasis on explicit comparisons. In fact, through Pierre Bourdieu's concepts of 'habitus' and 'cultural capital,' consumer choices are seen as predicated on taken-for-granted assumptions and internalized norms of appropriate taste ([1979]1984). Nevertheless, these taken-for-granted ways of perceiving the world and consuming are means of marking the social boundaries of class. Consumer choices, and the tastes that produce them, are a means of socially reproducing status differences. The following sections will trace the history of these concepts, their criticisms, and refinements.

Conspicuous Consumption

Interest in – and, often, social and moral concern with – what social scientists would now categorize as conspicuous consumption certainly predates the development of the concept. Roger Mason, for example, emphasizes early mercantilist concerns with ostentation (1998). As an academic discourse, Harvey Leibenstein notes that the Scottish economist John Rae was considering such purchasing behaviors in the first half of the nineteenth century (Leibenstein, 1950). However, it was Thorstein Veblen who popularized the theorization of such ostentation as 'conspicuous consumption' in *The Theory of the Leisure Class: An Economic Study of Institutions* ([1899]1912). Published toward the close of the American 'Gilded Age,' Veblen was writing during a period of both tremendous economic growth and growing inequality in the United States. Veblen saw waste, luxury, and pretentious displays of wealth as overarching themes of consumption under such conditions.

Andrew Trigg has noted that Veblen's theory was predicated upon this period of capitalist economic growth, pointing to Veblen's assertion that wealth generation and conspicuous consumption are linked. Once societies begin accumulating wealth, status displays through property gain significance for the maintenance of social position (Trigg, 2001). Wealth, while necessary for social status and esteem, was not enough: without displays of consumer goods and purchasing, there is no socially accepted means of proving wealth. Such public displays are necessary for two primary reasons. The first is what contemporary theorists call a moral hazard problem – there is a strong motivation to lie about how much wealth one actually possesses. The second is the existence of social norms that sanction boasting about ones wealth in an effort to gain status. As a result, transforming wealth into status goods provides a means of socially acceptable display that solves the moral hazard by providing verifiable evidence of wealth. Because these problems are enduring aspects of status-based societies, conspicuous consumption – both as a consumer practice and

a concept – has outlived the Veblenian era and context of America's Gilded Age.

The concept of conspicuous consumption fits within Veblen's larger stylized account of class society. Tracing the shifting meanings of class, status, and wealth across history, Veblen periodizes societies as 'savage,' 'barbarian,' and 'civilized.' For Veblen, distinct classes emerged during the period of 'barbarism' in feudal Europe and Asia, where wealth and status were linked to the spoils of war. However, with time, wealth came to be valued as a good in and of itself – such that inherited wealth could provide status above and beyond that attained by individual accomplishments. As a result, Veblen argued that in 'civilized' societies, displays of wealth aimed at attaining social esteem came to be the driving motivation governing individuals' practices surrounding work and consumption. In fact, he saw the desire for status as a more important determinant of consumption than even material needs. For Veblen, consumption was a thoroughly social phenomenon.

Of course, Veblen recognized that there were other potential solutions to the moral hazard problem surrounding wealth, and avoiding the social risks of boasting about wealth. Indeed, Veblen argued that where currency replaced more visible forms of wealth, the conspicuous display of a life of leisure emerged as an early solution. However, Veblen believed that humans possessed a productive instinct, such that idleness came to be seen as disreputable and was replaced by the acquisition of status goods. Gender features prominently in Veblen's account, with male heads of households seeking to maintain leisured wives who vicariously consumed lavish goods on their behalf. However, in the modern era, Veblen saw the endless cycle of competitive pressures toward conspicuous consumption as producing a societal strain. While conspicuousness began as an attempt to attain status, it increasingly took the form of a defensive effort to simply keep up.

In *The Theory of the Leisure Class*, Veblen saw consumption as 'conspicuous' in that it becomes an outward marker for economic wealth and social worth, and as a behavior driven by emulation and social comparison of taste. Of course, of central importance is the visibility of status goods. For Veblen, utilizing wealth for active status attainment only worked if the goods could become an outwardly verifiable marker one could compare with others. Emulation and comparison, while related, are two distinct arguments about the nature of consumer desire and behavior. By paying attention to emulation, Veblen suggests that consumer tastes are shaped by conscientious monitoring of similar others, rather than by stable individual preferences and rational concerns about the utility of consumer goods. For Veblen, no article will be worthy of consumption based upon its material utility alone ([1899] 1912: 157). Second, Veblen suggested that consumption was based on 'invidious' social comparisons: consumers enviously attempt to outdo similar others by looking upward to those of higher status ([1899]1912: 104). In essence, Veblen proposes a trickle-down theory of consumer tastes, in which the preferences of elites are reflected in the one-upmanship of those lower in socioeconomic status.

After Veblen's introduction of the concept of conspicuous consumption into the social science lexicon, the theory – and status-based models of consumption more generally – rose to become the predominant model for understanding consumer behavior in American sociology. For example, in the 1920s and 1930s, F. Stuart Chapin analyzed the living rooms of families' homes as measure of status. Strong reliability and validity were associated with using living rooms as a proxy measure of status, based on the Veblenian assumptions that living rooms are one of the most socially visible sections of a private residence, and that possessions serve as a reliable indicator of less visible – and, therefore, verifiable, socioeconomic status (Chapin, 1932). Even in the post-War era, Veblenian concepts of conspicuous consumption remained popularized in the work of economists such as John Kenneth Galbraith and Vance Packard.

The formulation of conspicuous consumption popularized by Veblen has undergone considerable refinement. For example, Harvey Leibenstein distinguishes between 'bandwagon,' 'snob,' and 'Veblen' effects in consumption (Leibenstein, 1950). As Leibenstein explains, the bandwagon effect refers to purchasing behavior in which consumer demand for a particular product is increased on the basis of other individuals' consumption of it. The snob effect, in turn, refers to situations in which demand for a good is decreased by others' consumption of it, as consumers seek to differentiate themselves from the masses. Finally, Leibenstein argues that Veblen effects are truly what qualifies as conspicuous consumption: such consumption occurs when individuals choose products on the basis of their higher relative price (Leibenstein, 1950: 189).

Even with such refinements, in more recent decades, the theory of conspicuous consumption has been the subject of considerable critical scholarship. Some, like Colin Campbell, have gone further by suggesting that the theory is not even testable, arising from the difficulties of matching consumer intentions with consumption choices (1995). For example, consumers may achieve the goal of status through other practices of consumption, or may make purchases for reasons unrelated to outdoing others but still end up doing so. Apart from criticisms surrounding the ability to empirically verify the concept of conspicuous consumption, Trigg has noted three distinct lines of criticism throughout its history: trends in consumption may begin at the bottom of the social hierarchy when those higher in socioeconomic status appropriate the styles of those below them; that consumption has become less conspicuous and status is now presented through avoidance of ostentation, and that models of conspicuous consumption based upon social status fail to reflect the identity projects that consumers undertake with their purchases (Trigg, 2001). While the first two critiques may very well be addressed by the acknowledgment of what Jeffrey Frankel has called the 'Bluejeans Effect' – the idea that the low price of certain goods, in and of itself, can increase demand as consumers seek to appropriate lower-class styles or demonstrate restraint (Frankel, 1975) – the postmodern critique has been more total. Douglas Holt, for example, has argued that postmodern consumption no longer rests upon acquiring consensual markers of status, but upon consumers' attempts to create lifestyles and identities (Holt, 2000).

Despite such critiques, recently some scholars have argued theoretically for the continuing analytic power of the theory of conspicuous consumption. Juliet Schor, for example, has

argued that the postmodern critique is not a sufficient basis for discarding status-based models of consumption (2007). She argues that researchers have yet to determine how independent of class position consumers' identity projects truly are, and that the presentation of a particular self-image through consumption is compatible with status models so long as consumers can read what symbolic meanings their choices will signal to others (Schor, 2007). Moreover, contemporary empirical studies continue to show Veblen effects in consumption choices. For example, Angela Chao and Juliet Schor have shown that found that women are more likely to buy expensive lipstick – since it is publicly applied – than face wash, despite the fact that price is not associated with higher material quality in lipsticks but is associated with superior face washes (1998). Moreover, Francis Bloch et al. have recently applied the concept of conspicuous consumption to the case of weddings in India, showing that a status-signaling model based on wedding size applied outside of the American context in which the concept was formulated (2004).

Despite empirical evidence that Veblen effects are still observable in consumer purchasing behaviors, Veblenian accounts of consumption remain contested. However, in many ways, the development of the concept of 'distinction' – with its inclusion of cultural capital and habitus – maintained a status-based model of consumption while addressing the critiques of intentionality.

Distinction

Amid the declining salience of Veblen's status-based account of consumer behavior in the United States, French sociologist Pierre Bourdieu introduced the concept of 'distinction' as a means of explaining the role of class in consumer and aesthetic preferences ([1979]1984). Taken alone, the idea of distinction is not all that different from the ideas behind the concept of conspicuous consumption. Both are predicated upon the idea that individuals mark their different statuses through their preferences and consumer choices. However, Bourdieu introduced the concepts of cultural capital and habitus as mechanisms through which class becomes operative in individual preferences. Fundamentally, Bourdieu asserts that cultural capital is the reserve of cultural and aesthetic knowledge an individual attains through his or her social position. Further, the habitus serves as the means through which cultural capital operates; it is the product of the internalization of such tastes and dispositions, such that preferences appear to the individual as natural and undirected, and often go unreflected upon.

These processes were of fundamental concern for Bourdieu since the ways individuals mark aesthetic differences through the classification of taste also mark differences between individuals: distinction is a means through which inequality is reproduced (Bourdieu, [1979]1984). Unlike Veblen, who was mostly concerned with conscious consumer choices made as a result of explicit comparisons, Michele Lamont and Annette Lareau explain Bourdieu's contribution of the concept of distinction as structural. In their survey of both Bourdieu's work and the earliest applications of the concept, Lamont and Lareau explain that Bourdieu's concern was not individual choices but the institutionalization of differentially valued tastes that function to reproduce social status and class (1988). Seemingly individual preferences, tastes, and dispositions are reframed as reflecting the differences between classes.

The early use of Bourdieu's concept of distinction and the related concepts of cultural capital and habitus revealed a dizzying array of applications and redefinitions, such that by 1988 – a mere 4 years after *Distinction* was published in English – Lamont and Lareau suggested the concept risked becoming meaningless (1988). Specifically, Lamont and Lareau argued that the concept of cultural capital – critical to explaining how distinction is attained through seemingly unintentional and habitual choices – had been employed to mean everything from human capital to high culture (1988). However, they argue that despite slippage in its application – and problems within the theory itself – Bourdieu's conceptualization was worth further theorization for its fundamental assertion that taste, as a distinguishing practice, provides a basis for exclusion and class reproduction (Lamont and Lareau, 1988).

As Schor (2007) has noted, Bourdieu's concept of distinction received an initial negative reception when it was published in English in 1984 in light of the declining use of status-based theories of consumption in the United States, such as Veblen's theory of conspicuous consumption. For example, Lamont and Lareau point out the frequency with which, outside of the French context in which the concept was developed, scholars were willing to dispense with the theory's fundamental concern with class reproduction in favor of a focus on status (1988). Despite recognizing value in the concept, specifically its focus on class reproduction, Lamont and Lareau themselves articulated strong critiques of distinction. For example, they argue that in complex societies, what counts as valued cannot possibly exist in a 'zero-sum' relationship to the dominated culture of lower-status individuals as a result of competing standards of evaluation. Further, they contend that lower-class standards of value can in fact operate autonomously and according to evaluative criteria opposing those of dominant, high-status groups (Lamont and Lareau, 1988). Such criticisms have allowed for more nuanced applications of the concept of distinction in recent years.

Recent refinements of the concept of distinction have come from applications of the concept outside of the French context in which the theory was developed – where scholars have argued consensually agreed upon hierarchies of status goods and tastes have become blurred. These scholars argue that there is no longer a definitive boundary between highbrow and lowbrow tastes. Instead, by the 1990s Richard Peterson and Roger Kern argued that taste and consumption were best understood as 'omnivorous' (Peterson and Kern, 1996). Such lines of research question the presumed homology between social status and taste present in the work of Bourdieu. Contrary to Bourdieu's assertion of discreet sets of classed tastes and dispositions (Bourdieu, [1979]1984), elites are recognized to consume across a much wider spectrum than in the past (Peterson and Kern, 1996). In a way, the conception of the one-dimensional consumer with tastes inextricably tied to class defies common sense; modern elite consumption is hardly as simple as a continuous stream of foie gras and Mozart. The elite no longer are conceived of as restricting their consumption to merely high culture, but are recognized as consuming across status lines.

The claims of omnivorous cultural consumption are supported by empirical work spanning a range of consumptive activities, demonstrating that the consumer seeking to portray cultural distinction is free to 'sample from a much broader cultural repertoire' (Johnston and Baumann, 2007: 200). Josée Johnston and Shyon Baumann, for example, trace the movement away from a hierarchical system of consensual status goods within the discourse of elite food consumption (Johnston and Baumann, 2007). However, the critique of the easily recognized, consensual hierarchies of status goods identified by Bourdieu as patterning consumption practices does not mean that the concept of distinction has been abandoned. Even in accounts of omnivorous consumption, distinction plays a prominent role. For Johnston and Baumann, for example, the ability of elites to consume widely across formerly discrete categories of high- and lowbrow foods and food experiences, and discern status value in a more open field of consumption, has become the new basis for status and distinction.

More recent critiques and refinements of the concept of distinction have benefited from the application of the concept outside of the European context in which it was initially developed and the American cultural milieu in which early applications occurred. Tuba Üstüner and Douglas Holt (2010), for example, suggest that studies of status consumption have been limited based on the assumption that empirical studies conducted in the United States and Europe could produce universally applicable, nomothetic models of causality in consumption. They argue that such a model merely extends the simplistic trickle-down model of status consumption advanced by Veblen, failing to integrate the more nuanced understandings Bourdieu's concept of distinction employed. While they recognize the global trickle-down model corrects for Bourdieu's assumption that status consumption occurred in cultural fields bounded by the nation-state, they seek to actively theorize how global efforts for distinction through status consumption play out in less industrialized countries. Specifically, their work suggests that some consumers must actively work to cultivate the type of habitus that will produce globally recognized forms of distinction, that cultural capital must be de-territorialized, and that the boundaries of consumption fields in a global context are inherently contested (Üstüner and Holt, 2010).

The Future of Conspicuous Consumption and Distinction

Since Veblen introduced the concept of conspicuous consumption into the social scientific lexicon at the close of the nineteenth century, theories of status consumption have maintained a prominent role in the ways social scientists conceptualize consumer behavior. The concepts of conspicuous consumption and distinction have many benefits over other models of consumption. Principally, they recognize the inherently social nature of consumption, and enable scholars to conceptualize the ways in which consumer culture helps to reproduce social inequality. However, as the histories of these theories indicate, these concepts are not without liabilities. For example, critics have rightly noted that fields of status consumption are not always based upon static, consensual hierarchies of consumer goods, that taste can operate at odds with the unidirectional trickle-down such concepts can imply, and that the concepts of conspicuous consumption and distinction often fail to account for the identity projects consumers undertake through their purchases. Likewise, the application of these concepts outside of the American and European contexts in which they were initially developed has further problematized them. While empirical studies have shown the simple applicability of status-based models of consumption in other contexts (Bloch et al., 2004), more detailed analyses have shown the very real limitations of conceptualizing particular models of distinction as universally generalizable (Üstüner and Holt, 2010).

Despite the many critiques of these status-based models of consumption across their intellectual histories, the current economic context suggests continued applicability and a chance for further scholarly refinement. The increasing stratification of society – both in the United States and globally – that resulted from the intense concentration of wealth beginning in the 1980s allowed for an expansion of markets in high-end, luxury items. While such changes have been noted by academics, they have also fueled a public discourse about consumer excess, particularly in the wake of the 2007 financial collapse. Many social commentators have begun to draw parallels to the Veblenian era in which the term conspicuous consumption first gained popularity. As in the Gilded Age, increasing economic stratification – a social process unlikely to be curbed with continued neo-liberalization and globalization of markets – may be fueling status consumption.

Whether status-based models of consumption, such as the concepts of conspicuous consumption and distinction, will regain salience in academic discourse remains to be seen. However, such conditions undoubtedly present a chance for refining such theories. Regardless, the critiques of these theories over the course of their intellectual trajectories have led to more nuanced understandings of consumer behavior – if only by serving as a foil for other approaches seeking to better understand the role of consumption in modern life.

Constitutional Courts

Brun-Otto Bryde, Justus Liebig University Giessen, Giessen, Germany

Abstract

In an increasing number of countries, specialized courts, rather than ordinary courts, are trusted to guarantee the binding force of the constitution. These specialized courts are commonly known as Constitutional Courts. This article describes their history with special emphasis on situations of constitutional transition, compares them to other organizations of constitutional control (American model, mixed systems, and international courts) and gives an overview of their composition and jurisdiction. In addition, it discusses their role in the political system and maps their place in sociolegal studies.

Constitutional courts (CCs) are specialized courts with jurisdiction over constitutional matters. In constitutionalist systems the constitution is considered to be the highest law with normatively binding force over political actors, including the lawmaker. While one may detect antecedents in antiquity and in English common law, the modern history of the 'higher law' nature of the constitution starts with the constitutions of the American colonies and the American and French revolutions.

On a theoretical level, it is the distinction between *pouvoir constituant* (lit. constituting power) and *pouvoir constitué* (lit. constituted power) (Sièyés) that establishes the constitution's binding force over the lawmaker. In more recent constitutional theory, the constitution is also regarded as providing supreme protection for the democratic process and for human rights against parliamentary majorities. Today, most constitutionalist democracies use courts to guarantee the binding force of the constitution. While many countries follow the example invented by Marshall in *Marbury v. Madison* and give this function to the ordinary courts, an increasing number use specialized CCs.

Constitutional Courts in Historical and Comparative Perspective

Democracy without Judicial Review

Judicial control of the political system is not a necessary feature of a democratic society. In systems with 'flexible constitutions' like the United Kingdom and New Zealand, the constitution is at the disposal of the lawmaker. In Israel, however, which has a flexible constitution in this sense, the Supreme Court has developed general principles, especially the principle of human dignity, which it uses to control the lawmaker. But even in countries with 'rigid' constitutions that are not at the disposal of simple majorities, the binding force can be conceptualized as a sanctionless imperative for the lawmaker. This was, for example, the case in France until the constitution of the fifth Republic introduced a (moderate) form of constitutional control.

In other constitutionalist democratic systems, judicial review is expressly excluded (e.g., The Netherlands, Switzerland on the federal level); still others know only an organized self-control of the lawmaker during the lawmaking process (e.g., Finland until 2000). However, the prominent examples of constitutionalist democracies without any form of judicial control are disappearing rapidly. Even the bulwark of parliamentarianism, Great Britain, has introduced a (very modest) form of judicial control of Parliament with the 1998 Human Rights Act. Increasingly, some form of judicial control of the political system has become a defining element of modern democracies.

Constitutional Control as Function of Ordinary Courts: The American or Diffuse Model

The introduction of judicial control by the US Supreme Court in *Marbury v. Madison* (1803) is not based on a constitutional authorization but rather on a logical conclusion drawn from the higher law status of the constitution. This power is, therefore, shared by all courts; there are no special procedures or remedies in constitutional matters, and decisions have no *erga omnes* effect. This system (called 'diffuse' in comparative constitutional law) has been adopted widely in legal systems whose constitutions are silent on judicial review, such as the common law countries and Scandinavia. Even though this system is regularly called the 'American' system, the US Supreme Court is in many ways an atypical case: it concentrates (through the *certiorari* system) on cases with constitutional implications, its judges are selected with their constitutional role in mind, and the *stare decisis* rule – the principle that relevant precedents are to be followed – gives its judgments a *quasi-erga-omnes* effect. In a sociological sense it acts very much like specialized CCs and is, therefore, included in many comparative works on constitutional courts, although it is not one in a technical sense. This is atypical for the diffuse system because for ordinary courts (including supreme courts) in such systems (e.g., in Scandinavia) constitutional questions are only a minor part of their function and judicial review is rarely exercised. Outside the United States only a few Supreme Courts of this type (most notably the Canadian Supreme Court, the Indian Supreme Court, and the Israeli Supreme Court) have assumed an active constitutional role.

Constitutional Courts: The Austrian or Concentrated Model

In contrast to the American model, CCs are the result of conscious constitutional design. Their history is usually said

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86012-2

to start in 1920 with the Austrian Constitution, based on a draft by Hans Kelsen (even though it was preceded by the Czechoslovakian constitution by some months). The power to find laws nonconstitutional was reserved to a special constitutional organ (therefore, this system is called 'concentrated'), and in its original version only federal and state governments could appeal to the court.

It is no coincidence that CCs were invented by Kelsen. They are, on the one hand, a logical correlate to a hierarchical view of the legal system. On the other hand, Kelsen's pure theory of law tries to shield law from politics; therefore, Kelsen was an opponent of the American model. In this perspective the creation of a constitutional court was not only an institutionalization of constitutional control but at the same time was a barrier to the development of judicial review by the general judiciary, as it could only be mobilized by a limited number of state organs for a constitution that did not contain a bill of rights. Here again the name-giving case of the 'Austrian model' is not representative: the vast majority of CCs created later were given much broader powers in constitutional systems with extensive substantive provisions. From a beginning with a much more restricted role than in the American system, today most CCs are more active political players than most courts in diffuse systems.

The rise of CCs began after World War II: CCs were important elements in the democratic reconstruction of Germany and Italy. Their model was influential in the third wave of democratization, beginning with Spain and Portugal, followed by the transformation in Eastern Europe in which CCs played an important role.

Constitutional reforms in other parts of the world similarly introduced CCs (South Korea, Thailand). South Africa gave its CC the unique function of certifying that the new constitution complied with the principles agreed to in the peaceful abolition of apartheid. In addition, other countries without a tradition of judicial review introduced CCs in constitutional reforms (*Cour de Arbitrage* in Belgium 1980 – since 2007: *cour constitutionnelle*). France created a restrictive form of preventive judicial control through a *Conseil Constitutionnel* in 1958. This model was adopted by some former French colonies in Africa (e.g., Burkina Faso, Ivory Coast, Senegal), but others have changed to a constitutional court system (e.g., Benin, Guinea, Mali, Niger). It is no coincidence that the development of CCs occurs during times of constitutional transition. In this circumstance, values and interests protected by old law come sharply into conflict with the legitimacy of the new constitutional order.

In this situation a CC has obvious advantages over the American model because the ordinary judiciary will often be compromised by its involvement in the old order. While it is extremely difficult to completely transform legal cultures just by introducing a new constitution, a specialized court composed specifically for this task, one that possesses an institutional commitment to the new constitution, can play a decisive role in bringing the inherited legal culture into conformity with the new model.

Mixed Systems

Some countries have left constitutional cases to the ordinary courts but have recognized the special nature of constitutional litigation by concentrating it in a supreme court or special chambers, by creating special constitutional remedies, and by decreeing the *erga omnes* effects of judicial review. Examples can be found especially in Latin America (because of the competing influences of civil law inheritance and North American constitutionalism). But in Latin America many countries have also established constitutional courts (Bolivia, Chile, Colombia, Guatemala.) There are also examples of mixed systems in Europe (Ireland, Estonia).

International Constitutional Jurisprudence

Since the end of World War II, judicial control of the political system has gained an international dimension. With a decisive innovative approach, the European Convention on Human Rights (ECHR) allowed individuals to sue their governments for violation of human rights in an international forum (a model later followed by the American and, recently, the African human rights systems). For countries without a bill of rights, the ECHR organs served as a kind of substitute CC (and the desire to create a local forum to precede international proceedings has influenced the move toward judicial review, e.g., in Great Britain). The European Convention is also important because in some countries without judicial control of constitutionality (e.g., The Netherlands, Switzerland) the conformity of laws with international human rights can be examined by the courts.

With the European community for the first time, an international organization created mandatory and binding court control over community organs and member states. The main function of the European Court of Justice is to safeguard the uniform application of European law, but it also can be considered a CC of the European Union.

Organization and Powers of Constitutional Courts: An Overview

CCs across the world employ a variety of mechanisms to ensure constitutional control.

Composition of the Judiciary

In general, the rules for the selection of judges tend to address their political function more openly than those of ordinary courts. They try to square the circle between providing for judicial independence and democratic legitimacy. A majoritarian solution (election by the majority of the day) creates the fewest theoretical problems for democratic legitimacy but endangers the control function. Attempts to reconcile the two aims include election with supermajorities (Germany) leading *de facto* to equal appointment rights between government and opposition, the distribution of nominating rights among different constitutional organs (Austria, France), and the inclusion of professional bodies in the nominating process (Italy). As the political element is stronger, appointment to CCs tends not to simply depend on advancement in the judicial hierarchy. Law professors and former politicians are especially highly represented. A relatively strong political influence on the appointment process is counterbalanced regularly by strong

guarantees for judicial independence. Appointment or election is either for life or long term.

Jurisdiction

In contrast to the American system in which the constitutional question can only be raised incidentally, during a case, in a CC system the constitution and constitutional court acts circumscribe the jurisdiction of the Court. Systems differ greatly in the extent to which they grant jurisdiction to CCs. As a means of objective control outside concrete cases, the power of abstract judicial review on application from privileged applicants (state organs, entities of federal systems, quorums of members of parliament) is perhaps the one most typical for CCs (and most distinctive compared to the diffuse system). In its most restrictive, purely preventive, form, the French *Conseil Constitutionnel* must be engaged in the short interval between parliamentary vote and promulgation, thus reconciling constitutional control with the maxim *la loi est la loi*. Much more common is repressive abstract review after the law has come into force.

Concrete judicial review allows other courts to refer constitutional questions raised in their proceedings to the CC, which holds a monopoly on finding laws unconstitutional. Access to the CC is most open where it can be mobilized by individuals (constitutional complaint, *amparo*) alleging violations of human rights (usually only after exhaustion of other remedies). In addition to handling human rights complaints, CCs adjudicate disputes between state organs or between the components of federal systems, have quasi penal functions (impeachment, prohibition of parties), and supervise the election process.

Constitutional Courts and Political System

In political theory the role of CCs remains controversial. Their power to overrule the decisions of elected representatives of the people is difficult to reconcile with the theoretical premises of majoritarian democracy. In countries with a CC the debate tends to be less heated than in systems where judicial review has been invented by judges, because the constitution makes express provision for jurisdiction. With the extension of judicial control in the last decades, rigorous opposition against it in the name of democracy has declined. Despite the theoretical merits of the majoritarian argument against judicial control over parliament, practical experience has shown it to be a workable reconciliation of majority rule with safeguards against the dangers of majority rule. The international human rights discourse has provided additional legitimacy to mechanisms that impose control over elected governments in the name of a higher legal order.

There remains, however, a permanent tension between the power of CCs to interfere in the political process, and the tenets of democracy. But the debate has shifted from the merits of judicial control in the abstract sense to its proper boundaries. In jurisprudence this debate centers on concepts like 'judicial restraint' and 'political questions', while social scientists study the political role of CCs and their impacts. In this debate, one of the oldest contributions, Justice Stone's footnote 4 in *Carolene Products* (304 US 144 [1938]), provides a valuable guide: the protection of the democratic process itself and that of 'insular' minorities not able to protect themselves in this process is easier to justify than the enforcement of competing value judgments.

The Sociology of Constitutional Courts

CCs (and constitutionally activist Supreme Courts) hold a special place in sociology of law. Their distinguishing feature is almost banal: they are very small. Different from other sociolegal court studies, with CCs one is not dealing with a social group but individually known actors. CCs apply a body of law that typically is more open textured and politically more controversial than normal law. These contrasts with other courts both facilitate and impede their sociological analysis. On the one hand, CCs offer case studies of the relationship between law and politics that make the relationship between judicial values and decisions impressively obvious. Therefore, sociology of law treatises often use constitutional jurisprudence to illustrate this relationship. On the other hand, they are so distinct from other courts that the application of sociolegal findings about judicial behavior to them is difficult, and generalizations from constitutional courts to other courts are dangerous.

Actors

Because of the political role of CCs, the politics of elections and appointments is an interesting subject of research that is in this case more directed to concrete selection processes than to generalized study of recruitment patterns. While there are correlations between known judicial background (including party politics, religion, status) and decision, there is no simple one-to-one relationship. The guaranteed independence (cf 3a *supra*) of CC judges has often resulted in disappointment on the part of selecting politicians. This can be explained by the self-image of judges and the institutional interests of CCs. For their impact in a political system, CCs rely heavily on their perception as neutral arbiters, and they would lose legitimacy if they appeared to be mere instruments of those who selected them. The high prestige CCs enjoy in many systems (especially compared with politicians) very much depends on this aura of independence.

Mobilization

One of the major differences between courts and elected policy makers is the fact that courts are reactive, not active, participants in the public arena. While this fact is often used as an argument by defenders of judicial review against majoritarians, it appears to be of limited significance as a barrier for judicial involvement in politics. In systems with very restricted access to the court (like in Kelsen's original model), it holds true. But access to most CCs tends to be much broader (3b supra) than the original model provided, and the different avenues combine to bring most politically controversial matters before, the courts. In light of the German Bundesverfassungsgericht accepting less than 2% of

the *c.* 6000 complaints received annually, one may assume that the court does not so much react but rather actively selects those issues it wants to address.

In addition, CCs are inventive in finding ways to involve themselves in politically sensitive subjects without regard to restrictions under procedural rules. In a related development, the more active courts do not restrict themselves to decide the case before the court but use *obiter dicta* to make long exhortations on future political action, thus departing from the judge's role of reactively deciding on the past and invoking instead the politician's role of actively influencing the future.

Decision Making

Similarly, the binding force of law cited (especially by lawyers) as a restriction of judicial power is less important for CCs than for other courts. Judicial decision making always has a political dimension, but it is subject to constraints intended to promote a specific juridical rationality and to hinder idiosyncratic decision making by judges. These constraints appear to be less effective with CCs. Their decisions are less strictly programed by law. While some constitutional law provisions (organizational norms, e.g., on elections) can be very specific, those texts that are relevant today in most constitutional proceedings – fundamental rights or constitutional principles – are very open textured (and traditionally in constitutional jurisprudence have been further expanded, rather than narrowed). CCs have to balance broadly worded rights against similarly broadly worded infringement clauses; they then must find the solution by balancing private rights against the public interest, using extremely open concepts (like the principle of proportionality), which give widest possible room for interpretation.

CCs have transcended the classical boundaries of judicial politics in another way. In principle, courts are different from political actors because they are restricted to yes/no decisions (lawful/unlawful) over past behavior, which is a powerful incentive for judicial restraint (e.g., if a CC had only the alternative of either, declaring a tax law void and risking public bankruptcy or accepting the law as constitutional). CCs have found ways around this problem. For example, they refrain from declaring laws void but order the lawmaker to change them in a given time. Or, they use the interpretation of laws or *obiter dicta* (i.e., nonbinding commentaries of a judge with only incidental bearing of a case) to enforce political compromises between proponents and opponents of a law under scrutiny. Such flexible forms of judicial decision free the court from the stark yes/no alternative and broaden its potential to actively involve itself in policy making by influencing future policies, building coalitions, and instigating political compromises. A promising strategy for measuring judicial activism appears, therefore, to be the study of the extent to which CCs have given up the ideal typical judicial style of decision making for a political one.

Abstract

Distinguishing the idea and practice of comparative constitutionalism from comparative constitutional law, this entry focuses on the historical roots and reemergence of comparative constitutionalism, which focuses on how constitutions are made, adopted, and used to structure society. It also discusses their legal existence and application within the political and legal practices of different countries.

Introduction

The idea and practice of comparative constitutionalism is a new field propelled by the political and technological changes of the late twentieth century (Jackson and Tushnet, 1999), yet it is rooted in antiquity, in the methodology of Aristotle and his students at the Lyceum. While not a well-established area of academic study (ACLS, 1990), comparative constitutionalism exists as a normative and legal practice as well as a form of comparative political and legal analysis. In contrast to comparative constitutionalism, comparative constitutional law has become a well-established and thriving discipline over the last decade (see Rosenfeld and Sajo, 2012; Ginsburg and Dixon, 2011). Nevertheless, comparative constitutionalism, which embraces not only the practice of comparative constitutional law but also the conceptualization and analysis of systems of governance that are based on the systematic allocation and control of power, remains a growing field.

Comparative constitutionalism is now widely practiced by both constitution makers and constitutional interpreters. Comparative constitutionalism became prominent in the late twentieth century, expanding exponentially in practice with the wave of constitution making that accompanied the end of the cold war. Constitutional reconstruction and amendment has continued to be a marked feature of national and international politics and law into the twenty-first century. Originating in the process of constitution making, in which participants sought to apply models and experiences from other contexts, comparative constitutionalism is perpetuated in the debates over the meaning of each new constitutional provision from the moment of its adoption. This practice is institutionalized in the jurisprudence of many constitutional and supreme courts who through their decisions effectively engage in a transnational comparative constitutional discourse on constitutional meanings and functions.

Academically, a single definition of comparative constitutionalism is difficult to construct. In philosophy, political science, and law, comparative constitutionalism is considered both a method of normative evaluation and an empirical and social scientific task of describing, contrasting, and reflecting upon the consequences of the different rights and institutional provisions of constitutions around the globe. As a normative exercise, the survey and comparison of constitutions remains close to the original Aristotelian method of comparing different constitutional provisions and institutions in order to define a better form of government. This approach has been supplemented with historical accounts that explore the development of constitutionalism over time (Pennington, 1993) and across national borders (van Caenegem, 1995). A normative emphasis is also prevalent in a range of studies that focus on some of the foundational questions underlying the adoption and implementation of constitutions: the relationship between constitutionalism and democracy (Elster and Slagstad, 1988; Habermas, 1996); the origin of the notion of fundamental rights and the role of civil society (Mamdani, 1991); and even the idea of a diversity of forms of constitutionalism that might be achieved through demands for cultural recognition in a postcolonial age (Tully, 1995). While increasingly of an interdisciplinary nature and central to the idea of constitutionalism, these studies tend to either focus on the conceptual and theoretical issues or adopt a country-by-country approach rather than a comparative perspective (Gordon, 1999; Pennock and Chapman, 1979).

However, with the emergence of globalization as both an empirical phenomenon and an object of study, the debate on constitutionalism has taken a comparative turn (Singh, 1989). Comparative constitutionalism in this latter sense reflects (or incorporates) two distinct approaches. On the one hand, there is a focus on comparing the different constitutional institutions that are employed to secure democratic forms of government (Sartori, 1994) or their role in shaping particular social issues such as identity and diversity (Rosenfeld, 1994; Habermas, 1998). On the other hand, there is an emerging focus on constitutional borrowing, adaption, and hybridization (Badi, 2000; Klug, 2000). The publication of two major works rooted in a comparative approach to constitutionalism has helped to further define this fledgling field (Hirschl, 2010; Jacobsohn, 2010).

Ran Hirschl argues for the recognition of a new legal form – constitutional theocracy – that he argues helps us to understand the coexistence of constitutional systems of government and a rising tide of theocratic authority that has undermined traditional notions of the separation of church and state that lies at the heart of liberal constitutionalism. Despite his fascinating analysis about the role of constitutional law and courts in bolstering secular forms of rule and his argument that there is "an intriguing conceptual affinity between constitutional law and religio[us] law, each with its own constitutive texts, interpretative hierarchies, and righteous morality alongside earthly interest" (Hirschl, 2010: p. 249), the most intriguing question

he posits seeks the source of conflict and change "within and between the religious and constitutional domains" (Hirschl, 2010: p. 17). Challenging the tendency in academia and popular culture to resist a political understanding of either law or religion, Hirschl points to the power of interpretation in both religion and law as a source of change; he also makes the argument that understanding the 'striking similarities' between these different symbolic systems may help us to understand how they evolve or "mutate to address social needs, economic interests, or political aspirations" (Hirschl, 2010: p. 239). While individual and collective identities might seem central to such a symbolic view of law and religion, Hirschl argues against the assumption of "firm identities and fixed group affiliations" (Hirschl, 2010: p. 45); instead he uses the facts of multiplicity in individual identities (as well as intra-group or intrafaith divisions) to emphasize the importance of politics, arguing that these markers of identity "may be brought to the fore or relegated to lesser status as coalitions shift, elites transform, and interests change" (Hirschl, 2010: p. 45).

This decentering of identity is in marked contrast to earlier works that either assumed that constitutions and their interpretation play a key role in the creation and evolution of national identities (Karst, 1989) or challenged the notion of a single national or constitutional identity and instead called for the recognition of a multiplicity of constitutional identities within particular constitutional orders (Tully, 1995). James Tully's argument for the recognition of a multiplicity of identities within modern constitutionalism resonates with Gary Jacobsohn's conception of the 'disharmonic constitution,' in which there exist both 'conflicting, even radically inconsistent ideas' (Jacobsohn, 2010: p. 3) and a broader constitutional identity – consisting of "identifiable continuities of meaning within which dissonance and contradiction play out" (Jacobsohn, 2010: p. 4). For Jacobsohn, the identity of any constitutional order fundamentally depends on the existence of constitutional disharmony, which serves as the catalyst of change.

This new scholarship on constitutionalism is premised on the idea that the constitution is not a particular historic document or even a legal structure but rather a broader regime that is constituted by a combination of legal commitments, institutions, and continuing political contestation over ideas and resources. In its comparative method it offers extraordinary insights into the structure and functioning of these varied constitutional orders. It also struggles to elucidate the mechanisms and pathways that have led to either gradual or dramatic change in different constitutional regimes. Instead of locating constitutionalism in a purely philosophical or normative discussion of appropriate forms of governance, these studies recognize its historical and institutional dimensions as key aspects of our conceptualization and debates over the place and role of constitutions. Instead of focusing our attention solely within the four corners of each constitutional document and the particular history and culture of the legal system in which it functions, this scholarship locates the discussion within the broader conception of constitutional orders – "a reasonably stable set of institutions through which a nation's fundamental decisions are made over a sustained period, and the principles that guide those decisions" – (Tushnet, 2003: p. 1) and the political realms these orders constitute and reflect.

The dispersal of sovereignty that is inherent in the process of globalization provides further difficulties for the definition of constitutionalism, as may be witnessed in the debate over citizenship and democracy in the European Union, or in the ideas of shared sovereignty that have been introduced into the debate over the future of Jerusalem. The post–twentieth century emphasis on the negotiated settlement of disputes over governance and power, whether at an international or local level, provides fertile ground for debating constitutional alternatives. At the same time, Stephen Holmes reminds us that "[c]onstitutions emerge and survive because, with a little help from their judicial friends, they serve the perceived interests of the best organized and therefore most powerful social forces. When the powerful discover the advantages they can reap from making their own behavior predictable, they voluntarily submit to constitutional constraints" (Holmes, 2012). From this insight he concludes that "[i]f you wish a constitutional norm to govern the way politicians behave, you need to organize politically to give ruling groups an incentive to pay attention and accept restraints on their own discretion for their benefit and yours" (Holmes, 2012). In other words, comparative constitutionalism can become a pragmatic alternative to continuing conflict.

The Global Context

Alarm over the Americanization of the world became a central theme for many critics of globalism in the 1990s. At the same time, many lawyers participated in and celebrated the new emphasis on the 'rule of law,' presuming the global adoption of law and legal processes as a precondition for successful transitions from authoritarian regimes and command economies into a new world order. The adoption of bills of rights and the empowerment of courts, which characterized many of these political transitions, led many to believe these developments reflected the embrace of American values in the post–cold war era. Bruce Ackerman heralded the emergence of a 'world constitutionalism,' arguing that the "enlightenment faith in written constitutions is sweeping the world" (Ackerman, 1997). Another prominent United States constitutional scholar, Cass Sunstein, argued that the "right kind of constitution could play an important role in fueling economic development and democratic reform; indeed, under current conditions, it may be indispensable to them"(Sunstein, 1993).

With the widespread adoption of constitutional forms genetically tied to the innovations of the American Revolution, it is not surprising that both advocates and detractors of the American experience assume the United States to be the hegemonic model. However, American lawyers and scholars participating in what was, in the 1990s, a more than billion-dollar program to promote the rule of law around the world found themselves in competition with alternative constitutional models. Although the bulk of activity in this rule of law movement focused on judicial and legislative reform designed to promote market economies, it is important to recognize that a central product of this dual process of political transformation and rule of law advocacy was fundamental constitutional reform in half the world – approximately 104 of the 188 members of the United Nations. Of these, a staggering

78%, or arguably 81 countries, adopted completely new constitutions.

Given a common belief in the United States Constitution as a "source of inspiration and ideas … studied and appraised by scholars, invoked by publicists, adopted or adapted by revolutionaries, nation builders and statesmen" (Henkin, 1989), many of those who joined the multitude of legal expeditions to the coal face of constitution making in Eastern Europe, Africa, and elsewhere were surprised to find themselves confronted with alternative constitutional models. Advocates of the American model found that instead of enjoying an unassailable status, they faced open competition from advocates of the German, Canadian, Indian, or other constitutional experiences. Given that these alternative constitutional experiences are to a large extent themselves based on the American model of constitutionalism, it is ironic that instead of serving as the dominant model, the American experience has become simply one of a number of alternative models. Yet this form of pluralism may be explained by the emergence of a practice of comparative constitutionalism. Constitution makers, interpreters, and litigants actively compared their own conditions and experiences with the current and historical experiences of other countries in order to advocate for one or another constitutional solution: whether a particular constitutional institution, the specific form of a constitutional clause, or the meaning of particular constitutional language. These practices became increasingly common through the 1990s as states around the globe engaged in one of the most profound processes of constitutional and political reconstruction ever. It is this context that has framed the new intellectual interest in comparative constitutionalism.

Constitutions, Constitutionalism, and the Politics of Comparison

The idea of comparative constitutionalism has shifted emphasis from a philosophical debate over the nature and form of good government to a more legal focus on the application and meaning of particular constitutional structures and rights, as well as the role of the judiciary in the project of limited government (Sajo, 1999). While the question of judicial review, and particularly the debate over the relationship between constitutionalism and democracy, dominated much of the academic discourse in the twentieth century, the changing social and political context has brought greater attention to the interaction of constitutional ideas and institutions across different legal systems and national boundaries (Schedler et al., 1999; Hanafin and Williams 1999; Teubner, 1997). This new trend is beginning to define a new field of comparative constitutionalism in theory and practice.

Comparative constitutionalism originated in the west with Aristotle, who in the *Nicomachean Ethics* made a case for the comparative study of constitutions, arguing that by studying the "constitutions we have collected … we shall perhaps be more likely to see which constitution is best, and how each must be ordered, and what laws and customs it must use" (Aristotle, 1996: pp. 1181b13-22). Although only the *Constitution of Athens* remains from this early venture, the product of this analytical exercise is presented by Aristotle in the *Politics* and remains a principal source for the study of comparative government, which still largely aims at the construction of a normative definition of institutional and political practices that are necessary in order to secure the good life.

The Aristotelian notion of constitutionalism (combining both a distinctive political order and the idea of a political regime in general) is, according to Carl Friedrich, the source of the "modern idea of a constitution as the organization of a government, its offices, and the relation of the offices" (Friedrich, 1968). For Friedrich, however, this understanding – which recognizes all forms of government as exhibiting one or other form of constitutionalism – was inadequate, for it incorporated dictatorial forms of governance within the idea of constitutionalism. Instead, Friedrich (1937), along with Charles McIlwain (1947) and Francis Wormuth (1949), emphasized the relationship between constitutionalism and individual liberty. For them, the essence of constitutionalism is not the organization of power but rather the idea of limited power. From the idea of restraints on power to the separation and division of power, the focus among Anglo-American theorists through the middle decades of the twentieth century was on the guarantee of individual liberty, which they took to be the product of various means of limiting state power (Pound, 1957).

Writing first in the shadow of Nazi Germany and then in the aftermath of World War II, and during the cold war, Friedrich shifted the focus away from the comparative perspective inherent in the Aristotelian approach by posing the question: What is the political function of the constitution? From this starting point, Friedrich identified the protection of the individual member of the political community as the primary object of constitutional government, thus redefining constitutionalism as a 'modern phenomena' whose central concern is the practice and theory of limited government (Friedrich, 1937, fourth ed., 1968). This focus empowered Western theorists to reject constitutional forms, particularly the 'symbolic' state socialist constitutions that failed to limit state power, as aberrations of the constitutionalist tradition. Thus constitutionalism was once again given a normative form but at the cost of limiting the concept to only those constitutional arrangements that successfully limited and controlled state power.

The failure of postcolonial constitutions in Africa (Nwabueze, 1973; Okoth-Ogendo, 1993) and other parts of the third world, despite the inclusion of clauses formally limiting, separating, and controlling state power, produced an alternative, sociolegal approach to constitutionalism. Legal academics and political scientists argued that it was important to understand the economic and social context that determined the effective constitution of power in these newly independent states (Ghai, 1991). Taken further, this analysis seeks to demonstrate how the underlying colonial and neocolonial conditions of social organization, particularly the dual legal system and lack of land tenure security, restrict the capacity of civil society in Africa (Mamdani, 1996; Shivji, 1998). Without changes in these conditions, it is argued, the notion of legal rights against the state and restraints on state power are ephemeral. Despite this disillusionment with formal constitutions and constitutionalism, struggles for democracy and interethnic strife in many developing countries has fueled

a continual search for understanding the place constitutionalism may play in the reconstruction of postcolonial states. Yash Ghai, for example, has sought constitutional solutions to problems of ethnic strife, both in his practice as a constitutional advisor and in his academic work (Ghai, 2000). He has also applied this sociolegal perspective to analyzing the role of constitutional formulations produced to define the relationship between the central government in China and a reintegrated Hong Kong (Ghai, 1997).

With the protection of the individual as its central goal and the restraint of political power as its essential feature, the study of constitutionalism lost steam in the Anglo-American world, splitting in two distinct directions, one legal and the other political. On the legal side, there developed an interest in judicial review as the central concern of legal constitutionalists. Here the idea of comparative constitutionalism became, and remains to some extent, equated with comparative constitutional law (Cappelletti and Cohen, 1979). In this context the comparative approach focuses either on the specific problem of judicial review, engaging in a comparison of the process of judicial review exercised by courts around the world (Cappelletti, 1989), or compares the case law of different jurisdictions in order to explore different means of constitutionally resolving particular issues from the protection of property rights (Allen, 2000) to abortion and hate speech (Jackson and Tushnet, 1999). On the political side, the fiscal crisis of the state and political conservatism in the late 1970s and 1980s led to a direct political attack on the role of the state in society. Despite challenges of cultural imperialism by those advocating an 'Asian-model' of autocratic paternalism or those who argued that "constitutionalism is largely a cultural phenomena and not simply the product of properly designed institutions and structures of government" (Franklin and Baun, 1995), the emphasis upon the need to restrict state power created an intellectual and political environment in which the constitutional protection of individual rights and the institution of judicial review became the dominant features of a post–cold war international political culture.

The emphasis on the legal form of constitutionalism, and judicial review in particular, shifted the focus onto the role of the judiciary, encouraging both a practical emphasis on judicial reform as well as an interest in the global expansion of judicial power (Tate and Vallinder, 1995). However, at the same time, the failure, and even collapse, of governments in Africa as well as the Asian economic crisis in the 1990s brought a renewed focus on the question of power and the need for effective governance. This focus raised the question of how the constitutional allocation of power should in fact empower the state to achieve the necessary capacity to secure a level of social coordination necessary to the achievement of the already acknowledged constitutionalist goals of individual security and freedom.

The Problem of Governance and the Role of Comparative Constitutionalism

If constitutionalism is historically the struggle to regulate political competition, then it is unsurprising to discover that different constitutional options in fact reflect continuing ideological and political alternatives. The politics of constitution making (Elster, 1995) is thus festooned with the claims of competing political groups who project their ideological perspectives and political goals into constitutionalist forms (Klug 2000). While the post–World War II response to the violation of human rights produced a movement that could insist on the recognition and promotion of human rights through both international and domestic fora, the reemergence of a nineteenth-century liberalism, in the guise of 1980s neoliberalism, had profound implications for the politics of constitution making in the post–cold war era. In this context Friedrich von Hayek's conception of politics as threatening a liberal order that is simultaneously complex and delicate (Hayek, 1960) provided a central argument for those who sought to shrink the state. Although democratic theorists and constitutional scholars had long highlighted the anti-democratic implications of constitutional review, the neoliberal project emphasized the rule of law – requiring an independent judiciary with powers of judicial review – and demanded a constitutionalization of many other institutions and areas of governance as a means to limit the destabilizing impact of politics.

Despite the gains made by neoliberalism at the end of the cold war, the politics of constitution making remained eclectic. Although the vast majority of states undergoing reconstruction through processes of constitutional change in this period seemed to accept the liberal paradigm of individual human rights and multiparty democracy, this did not preclude the simultaneous inclusion of a range of alternative constitutional elements, including socioeconomic and cultural rights, reflecting alternative traditions. Significantly, the dominant liberal democratic tradition itself contains different trends, sometimes complementary, sometimes contradictory, advanced by different social forces and reflecting a plurality of interests. Of these, the two trends with the most direct impact on processes of post–cold war state reconstruction were those emphasizing liberty and equality. While there is a significant overlap in liberalism's ideological commitment to liberty and equality, emphasis on one or the other provides a range of alternatives within the liberal democratic tradition. These extend from classic nineteenth-century liberalism with its emphasis on individual freedom and property rights to the claims of the democratic collectivity inherent in the social democratic liberalism of the post–World War II era. While both aspects of this tradition emphasize electoral democracy and the protection of individual rights, they also contain contradictions with important consequences for the shape and role of the state.

While the struggle for equality, whether aimed at economic or racial inequalities, elicited the power of the state to address entrenched private power, the struggle for individual freedom has eschewed the state, often characterizing governmental power as the very source of oppression. These different responses to the state have obvious consequences for the structure of government, the most dramatic being the emphasis on the need to downsize or limit the role and capacity of the state. Combined with a reaction against the commanding role held by the state in state socialist societies

and strengthened by the fiscal crisis of the state in western democracies, this tendency achieved a significant degree of influence in shaping the international political culture that framed the post–cold war process of state reconstruction. By contrast the classic elements of a social democratic state, including the state's social welfare orientation and regulatory role in the relationship between capital and labor, including the creation of corporatist institutions that gave organized labor an important voice in social organization, fell into political and ideological disrepute, and began to be dismantled.

It is in this context that comparative constitutionalism provides an opportunity to rethink many of the longstanding assumptions about traditional constitutional forms so as to understand their role in the construction and maintenance of different constitutional orders. There are three sets of values that frame traditional notions of constitutionalism: (1) federalism, or the spatial division of power; (2) the separation of powers between different branches of government; and (3) the notion of constitutional rights. Each of these addresses different aspects of the 'problem' of power – its allocation, application, and restriction – within the nation state. While these constitutional values, with their diverse historical origins, have become increasingly universalized, their application in increasingly varied historical, cultural, and political contexts has produced a diversity of approaches and understandings that provide a diverse global text for political actors, constitution makers, constitutional interpreters, and litigants.

The Practice and Theory of Comparative Constitutionalism
